PREVENTION OF BIRTH INJURY AND ITS RESULTING MORTALITY

FROM THE STANDPOINT OF THE OBSTETRICIAN

CHARLES EDWIN GALLOWAY, M.D.
EVANSTON ILL

As one reviews the subject of birth injury and studies one's own cases, one begins to wonder as a recent English author has said, whether it is not true that one of the greatest risks that the human being ever assumes is his passage through the birth canal.

Birth injury may occur in any type of delivery. It is very essential, therefore, that a careful explanation be given to parents, and the most valuable explanation of course, comes from the consultant who is not present at the birth. This consultant is most often the pediatrician.

The incidence of birth injury is very difficult to ascertain. Nor can any one say whether it is on the increase or the decrease, for one is able to find in the English literature only a few accounts of analyses of large numbers of cases and classifications of birth injuries.

At the Evanston Hospital, investigation of the last 5,000 deliveries reveals the fact that there were fifty-one major injuries including fatal cerebral hemorrhage. Besides these there were thirty-seven minor injuries including abrasions from forceps and other contusions of minor importance. At the same hospital an analysis of the fetal autopsies for the last ten years shows that 34 per cent of these fetal deaths including premature babies were due to cerebral hemorrhage. It also shows that 40.6 per cent of the autopsies on full-term babies dying at birth demonstrated cerebral hemorrhage.

W. H. Taylor has shown through compilation of various autopsy records that in approximately 30 per cent of all fetal autopsies cerebral hemorrhage is found to be the principal cause of death. These figures are presented in table 1.

Of the various injuries cerebral hemorrhage, no doubt, occupies the primary position as to both severity and mortality, and since it is probably the most common injury it will be discussed first.

CEREBRAL HEMORRHAGE

The old saying that the baby dies below the tentorium seems to have been demonstrated both by clinical and by laboratory evidence. None of the supratentorial part of the brain seems essential for life. As Crothers¹ has said, "the integrity of a small block of tissue lying between the third thoracic vertebra and the tentorium determines whether a baby is alive or dead when born."

The exact mechanism by which this particular injury is produced cannot always be explained. Injuries to the brain must be looked on as an interaction of a variety of factors.

Direct therapy or possible prevention of such injuries is confined to the control of pressure and indirectly to the preservation of the continuity of pressure in the various cranial vertebral cavities. It is interesting to note that new-born animals with thick skull bones and no fontanels do not have intracranial lesions. The precise manner in which the tentorium or other intracranial structures are torn does not seem to be important. About all that is known concerning the etiology of cerebral hemorrhage can be summed up in four statements: 1. Distortion of the head causes underlying sinuses to be partially compressed with resulting disturbances of intracranial blood circulation. 2. Compression of the head in one direction causes a compensatory elongation in other directions and this strain is most marked along the free edges of the tentorium. 3. Negative pressure causes a suction effect on the presenting part of the head in vertex presentation and on the uppermost part of the head in breech presentation. 4. The character or strength of the tissue put under stress is an important determining factor.

Bearing these points in mind, it is quite evident that nothing should be done to hasten delivery until the head is visible or on the pelvic floor. The use of solution of posterior pituitary and other drugs to cause more rapid descent of the head is contraindicated.

Episiotomy is indicated in order to relieve pressure as the head comes through the narrow vaginal opening, especially in cases in which the baby is premature.

Premature rupture of the membrane either for induction or to hasten labor seems contraindicated because of the negative pressure exerted on the presenting part.

There are cases encountered in which the heart tones gradually or suddenly become slower about the time the head reaches the midplane. In many cases this is, no doubt, due to intracranial pressure. Application of forceps will only have a tendency to increase the pressure.

Ether many times relieves uterine contractions, and the resulting relaxation will lessen cranial pressure and the fetal circulation may improve.

Outlet forceps in conjunction with episiotomy will probably result in fewer cerebral hemorrhages. If forceps are used, it is much less dangerous to make a cephalic application than a pelvic application and it is also quite essential that there be no squeezing with the blades. If necessary, a towel or set-screw should be used to prevent such squeezing when effort to extract the head is exerted.

After a long labor in which molding of the head has occurred to a marked degree, such a molded head should be released quite slowly.

¹ Crothers, Bronson. Obstetrical Injury of Spinal Cord. Boston M. & S. J. 196: 397 (March 10) 1927.

Another contributing cause is a violent attempt to resuscitate the baby, especially Schultze's swinging

Many obstetricians as a routine procedure give the baby an injection of 20 cc of whole blood in the thigh following all difficult deliveries. It is thought that this procedure lowers coagulation time and thereby helps to prevent what would become a dangerous hemorrhage from a point at which slow oozing is occurring. There is as yet, however, no definite proof that the procedure has lowered the fetal mortality but it has been practiced for some time and, I think, will continue to be by most obstetricians.

Another contributing cause, and one that is probably considered by most men is a too prolonged test of labor. Since cesarean section now carries a satisfactorily low risk, it behooves the obstetrician to use it oftener in cases in which the pelvis is known to be abnormally flat or small rather than to allow the baby to develop a cerebral hemorrhage in an attempt to see whether the uterine contractions can force the head through the inlet. The same can be said for the second stage of labor with the head deeply engaged. Delivery should be effected with episiotomy and forceps generally within two hours. Further delay only tends to raise the mor-

tality. The stubborn obstetrician is the cause of cerebral hemorrhage in a certain number of cases just as the hasty obstetrician is contributing to its prevalence.

In this study of 5,000 deliveries there were 222 cesarean sections. Two babies showed symptoms of cerebral irritation but recovered and were discharged apparently well. Both cases had had a test of labor. Two other babies were cut with the scalpel when the lower uterine segment was being opened. These were the only injuries among this group of 222.

BRACHIAL PALSY

Injury to the brachial plexus is generally due to stretching of the first and sixth cervical nerves and nerve roots. The injury in some cases is due to pressure between the clavicle and underlying bone structures and also to a primary injury of the shoulder joint or humerus. It is therefore quite necessary that the

obstetrician use as little force as possible on the head in vertex presentations and in such an event light anesthesia seems indicated, as the uterine contraction will be more likely to deliver the shoulder. That injury is being done by those delivering babies is quite evident from the fact that new cases are being reported.

Crothers made the statement only a few years ago that sixty new cases a year show up in one clinic at the Children's Hospital in Boston.

Dropping the end of the bed and Kristeller expression are both useful maneuvers in delivering the shoulders. Sharp angulation of the spine in breech contributes to this injury, and the pressure of the fingers on the neck and shoulders of the baby during breech extraction is one of the most common causes.

We have had only four cases of brachial plexus injury in the last 5,000 deliveries and they were all quite mild. The symptoms lasted only from a few hours to a few days. Three were delivered with forceps and one was spontaneous.

FRACTURED CLAVICLE

Muus found an incidence of 1.5 per cent for fracture of the clavicle in 1,700 living babies and it was most common among multiparas. Twenty-two cases that he reported were divided as follows: seventeen spontaneous and five breech.

Hukewytch in 1929 found thirty-two fractures of the clavicle in 2,213 deliveries. Both of these figures would seem rather high, as I was able to find only fourteen fractured clavicles in the last 5,000 consecu-

tive deliveries, which gives an incidence of 0.28 per cent. The relative number of fractured clavicles in breech seems much higher than in vertex presentations. Operative delivery seems to contribute practically all fractures of the clavicle. We had only one case in the spontaneous deliveries, whereas there were thirteen in babies delivered either with forceps or by breech extraction.

The operator should avoid traction on the head or neck. In vertex presentation the finger should reach for the axilla as soon as possible, and light rather than deep anesthesia seems indicated.

FACIAL PARALYSIS

Facial paralysis occurs most often in forceps delivery, owing to the pressure of the blades on the tissues surrounding the facial nerve. It may be central however, because either of cortical or of intramedullary hemorrhage. It has also occurred in spontaneous delivery especially when there was a flat or contracted pelvis. Unless central in origin, the paralysis disappears in from a few minutes to a few days.

The forceps blade should not be too thin; the cephalic curve should not be too sharp, and a sliding blade will sometimes permit a better application to an asynclitic head.

STERNOMASTOID MUSCLE INJURY

Wryneck noticed at birth is a true congenital anomaly in practically all cases. Trauma as the cause is very exceptional. The pathologic state of the sternomastoid muscle is probably due to an anomalous attitude of the head, and this faulty attitude may favor presentation by the breech. Comparatively slight traction suffices to lacerate this abnormal muscle, but the laceration may even improve its condition.

RUPTURE OF THE LIVER

Rupture of the liver is generally due to some abdominal manipulation while an attempt is being made to convert a faulty presentation into a more favorable one. It may occur also in version or breech extraction or in an attempt to assist a delivery by external pressure. The relatively large size of the liver in the newborn is probably a contributing factor. These babies are symptom free at birth and die suddenly about the third day when the capsule breaks as the result of the increasing pressure within the liver. A fairly large intra-abdominal hemorrhage is found at autopsy.

BREECH DELIVERY

Breech delivery and version with breech extraction show a higher incidence of birth injury than any other type of delivery. The fetal mortality is also correspondingly high. A recent report from the Brooklyn Gynecological Society shows that birth injury occurred in 2 per cent of "spontaneous breech assisted," 5 per cent of "breech extraction" and 9.9 per cent of "breech broken up." The report covered all breech deliveries in thirty-two Brooklyn hospitals from 1926 to 1930 inclusive but did not include breech delivery following podalic version. The fetal mortality among babies weighing over 2,500 Gm., after taking out twins, congenital defects, prematures and macerated fetuses was 12.6 per cent.

Several pertinent facts should be mentioned relative to breech extraction. The unnecessary haste displayed by the average operator seems most objectionable and the next most undesirable factor is the lack of complete relaxation and dilatation of the soft parts. Breech

extraction calls for complete dilatation and deep ether anesthesia. Episiotomy is called for in practically every case.

During breech extraction the operator should avoid pressure on the fundus, extreme angulation, excessive suprapubic pressure and dangerous traction. It is possible to elongate the spinal column about 5 cm., and the thoracic cord of the fetus is only about one-eighth inch (0.3 cm.) in diameter. The cord is enlarged in the cervical and lumbar region and is well anchored by the brachial plexus above and the cauda equina below. It is for these reasons that extreme traction causes thoracic cord injury in some cases.

THE TREATMENT OF ACUTE NICOTINE POISONING

F. E. FRANKE, M.D.

AND

J. E. THOMAS, M.D.

ST. LOUIS

The fact that an individual poisoned with nicotine is rarely seen by the physician in time to institute treatment is not a sufficient reason for a lack of knowledge as to what may be done to save life when the opportunity is at hand. Except for the usual procedures to remove any unabsorbed poison and the administration of stimulants, we have been unable to find in the literature any description of a rational treatment for nicotine poisoning. Generally the condition is considered hopeless. This pessimistic attitude is apparently due to the belief that the drug causes generalized paralysis of the central nervous system based on the fact that complete muscular paralysis, loss of reflexes and paralysis of respiration (and finally of circulation) follow its absorption in sufficiently large doses. As Moore and Rowe¹ have pointed out, all these effects could as readily be due to the curare-like action of the drug as to central paralysis. As a result of experiments on dogs,² we are convinced that death from nicotine poisoning is due to peripheral paralysis of the respiratory muscles when convulsions are prevented, and if these occur to fixation of the respiratory muscles.

We were unable to elicit any clear evidence of paralysis of either the respiratory or the vasomotor center during the convulsive seizures.

At the 1935 meeting of the American Society of Pharmacology and Experimental Therapeutics, Gold and Brown³ of Cornell University presented strong evidence that nicotine poisoning in the experimental animal causes a peripheral rather than a central paralysis of respiration.

Unpublished experiments carried out under the direction of one of us (F. E. F.) show that the paralysis of reflexes is peripheral rather than central, indeed, that the reflex excitability of the spinal cord is retained even in the presence of nicotine in many times the fatal dose.

Furthermore, experiments herein reported show that nicotine does no evident irreparable damage to any of the structures on which it acts and that the administra-

tion of very large doses is not incompatible with reasonably prompt and apparently complete recovery when appropriate treatment is instituted in time. For these reasons, nicotine poisoning should, we think, be regarded as a temporary respiratory emergency comparable to drowning (or electrical shock) and should be treated as such. We have undertaken to determine the results that follow the application of the methods of treatment in common use in acute emergencies of the type mentioned following the administration of nicotine to dogs in doses that ordinarily prove fatal.

CLINICAL LITERATURE

On reviewing the literature we find seventy deaths⁴ from nicotine in rather concentrated solutions and from tobacco. We are supplementing this list with four fatal cases occurring in St. Louis which have not been previously reported. The deaths from nicotine usually occurred within a few minutes after its ingestion. In only one of twenty-eight fatal cases was treatment attempted. An endeavor to administer an emetic was unsuccessful because the patient's jaws were clenched.

Death did not occur so quickly in the forty-six fatal cases of tobacco poisoning. Alcohol was used in five cases, gastric lavage in three, artificial respiration in two, ammonium carbonate in two and the remaining procedures were tried once each, friction, saline hypodermoclysis, atropine, aqua ammoniac and stychnine.

Artificial respiration was used in two cases, along with stimulants, whisky and elimination. In the Weak's case, artificial respiration was begun after the heart and respiration had apparently stopped and the patient

revived. The artificial respiration was continued for at least five of the next seven hours. Thirty minutes after the artificial respiration had been discontinued the patient suddenly died. In the Reynolds⁶ case artificial respiration was resorted to on several occasions when the respiration became very slow. Several hours later, when the patient's condition seemed quite favorable, respiration suddenly ceased and on immediate investigation the heart was found to have stopped beating.

The value of artificial respiration is strikingly illustrated in the following case. Dr. Bleasdale⁷ was called in to see a boy, aged 2 years, whom he found in a dying condition. The boy, a strong sturdy little fellow, had been given a tobacco decoction rectally for the cure of worms. The physician found the child comatose and pulseless, and the breathing had almost ceased. The boy's pupils were widely dilated and insensitive. Artificial respiration was administered at once and kept up for about one hour during which time others present administered soap and water enemas and afterward, biliary by rectum. For the first twenty minutes there was little effect and whenever artificial respiration was stopped the patient did not breathe. Gradually there was a change for the better and at the end of about forty minutes the child vomited. After this the improvement continued and the artificial respiration was discontinued at the end of an hour. Three hours later the child had completely recovered from the effects of the poison except that he complained of feeling tired.

Removal of the poison is, of course, indicated. McNally⁸ reports a case of recovery following the ingestion of a concentrated nicotine solution. He attributes the recovery to the profuse vomiting and gastric lavage, which was carried out. Emetics may be effective in removing pieces of tobacco that will not pass through the stomach tube.

Esser and Kuhn⁹ describe a case of recovery following the ingestion of 4 Gm. of pure nicotine. They attribute recovery to the fact that the patient had taken food previously and to the copious and persistent vomiting that occurred.

Coffee, ammonia and artificial heat have been used in a number of cases in which recovery occurred. At a time when tobacco was used therapeutically, whisky was often used as a stimulant.

While the fatal dose of nicotine is very small, Sollmann¹⁰ giving one drop (65 mg.) as the minimal fatal dose yet individuals have ingested much larger quantities and have recovered. Vomiting generally occurred or gastric lavage was carried out.

Through the courtesy of the health commissioner of St. Louis Dr. Bredeck we inspected the records of the coroner's office for a period of ten years ended in 1933 and found four deaths from nicotine poisoning. A brief account of these cases follows.

T. H. July 24, 1926 committed suicide by drinking a nicotine insecticide. He was seen taking the insecticide fell to the floor and asked for a doctor. He died in an ambulance on the way to the hospital.

J. C. Dec. 28, 1928 was found dead in bed. On the floor nearby was a 2 ounce (30 cc.) bottle which contained nicotine. He had threatened suicide.

F W H, a man, aged 54, a truck driver, went to the basement of his home June 8, and ten minutes later returned upstairs holding his abdomen and shortly after fell to the floor. Attempts to get him to swallow milk were unsuccessful, for he had lost consciousness. The patient was apparently dead by the time a physician arrived. A half pint whisky bottle partly filled with nicotine was found on a table in the basement. The coroner reported the death as due to nicotine solution, whether it was taken accidentally or intentionally was not ascertained.

J W, a boy, aged 3 years, was playing in the kitchen and when the woman watching him had turned her back he took a bottle containing "nikoteen" insecticide and drank part of its contents. She took him to a hospital less than a block away where he died a few minutes later. An autopsy was performed but the stomach contents were not analyzed.

Essex and Kühn⁹ point out the increasing incidence of nicotine poisoning in recent years. McNally found five cases of fatal nicotine poisoning in Cook County, Ill., in a period of two years, and we are reporting four cases in a period of ten years in the city of St. Louis. If one assumes that such a ratio of nicotine deaths to population holds true for the United States as a whole there are more than 500 deaths in a ten year period instead of the much smaller number that we have found in the literature.

METHODS

In all but one of the experiments herein reported the nicotine was either dropped into the mouth in the form of the undilute alkaloid or injected into the circulating blood in 10 per cent solution. It was given intramuscularly as the hydrochloride in one instance. The injections were made either into a vein or into the cavity of the left ventricle. Both anesthetized and unanesthetized dogs were used.

The results of the following methods of treatment were observed: artificial respiration alone, artificial respiration with intracardiac injection of epinephrine and indirect massage of the heart, and artificial respiration and direct massage of the exposed heart, with or without intracardiac injection of epinephrine. The epinephrine was given in doses of from 0.2 to 1 cc of the 1:1,000 solution, according to the size of the dog.

The artificial respiration consisted of positive ventilation of the lungs by means of an interrupted current of compressed air. The air was supplied to anesthetized animals through a close fitting tracheal tube and to unanesthetized animals through a face mask made air tight by means of petrolatum cotton packing. When artificial respiration alone was relied on it was started before the circulation and respiration had failed. The other measures were used to resuscitate animals that were apparently dead.

RESULTS

A. Artificial Respiration Alone—Artificial respiration without other treatment was tried in sixteen experiments on unanesthetized animals (table 1). In fourteen of these it was begun shortly after or (in one animal only) just before the nicotine was administered and while the pulse was still palpable, or when the blood pressure was being observed before it had fallen below the normal level. In all these fourteen experiments the animals lived as long as the artificial respiration was continued. Ten of them recovered completely and survived till used for other purposes. In two the artificial respiration was stopped before recovery and two were killed later with a second dose of nicotine. Seven of these animals were given nicotine in doses that had proved uniformly fatal in other animals,¹¹ and six of

these were in the group that survived indefinitely. According to our results with similar doses in other experiments, three fourths of the other animals would have died if artificial respiration had not been given.

Artificial respiration was started in two experiments after the circulation had failed, that is, after the pulse was no longer palpable in one instance and while the blood pressure was falling rapidly and had reached 60 mm in the other. No improvement was noted in these animals, and the heart ultimately stopped in spite of the artificial respiration.

There were no signs of circulatory failure in the group of fourteen animals as long as the artificial respiration was continued. The pulse was of good volume and the blood pressure, when observed, was generally above the normal level during the first half hour but slowly returned to the normal level. If the artificial respiration was stopped the blood pressure rose slightly at first and then fell rapidly, as in ordinary asphyxia. However, we got the impression that the circulation failed rather more promptly in nicotineized animals after the respiration had been stopped than it does in simple asphyxia. We have no data on the length of time that normal animals survive asphyxia and are therefore unable to make a direct comparison. Generally one minute of asphyxia was sufficient to cause an alarming fall in the blood pressure of the nicotineized animals, especially if allowed to develop soon after the nicotine was given. Later the animals were able to survive two minutes or more without artificial respiration, but this was probably because, having partially recovered from the effects of the nicotine, they made some spontaneous respiratory efforts.

B. Artificial Respiration, Intracardiac Epinephrine and Indirect Cardiac Massage—This treatment was employed as a means of resuscitating animals that were apparently dead following the intravenous or intracardiac administration of a fatal dose of nicotine. Sixteen animals were treated in this manner (table 2). Twelve of these were in the surgical stage of ether anesthesia when the nicotine was given and four were unanesthetized. The treatment was begun in these animals only after respiratory movements had ceased and the heart beat could no longer be detected by palpation either of the pulse in the femoral artery or of the heart through the chest wall. In our rather large experience no animal has recovered without treatment after this stage has been reached, and we are convinced that spontaneous recovery does not occur after the heart action and respiratory movement can no longer be detected by external observation. The size of the dose is therefore of less importance in these experiments than in those described in the previous section for the reason that the dose, though in some cases less than the certainly fatal dose, proved to be a fatal dose for the particular animal to which it was given.

Most of the animals were prepared for artificial respiration before the nicotine was given, so that this part of the treatment was generally started promptly as soon as we had satisfied ourselves that the circulation and respiration had positively failed. The administration of epinephrine and the beginning of cardiac massage were occasionally postponed for a few minutes to test the efficiency of artificial respiration alone. As stated previously, artificial respiration alone was uniformly ineffective after circulatory failure. The time from the giving of nicotine till the beginning of each of the aforementioned procedures is given in the table.

¹¹ Franke, F. E. and Thomas, J. E. *Proc. Soc. Exper. Biol. & Med.* 29: 1177 (June) 1932.

One half of the animals were successfully resuscitated and, with one exception, restored to normal. This one animal was apparently recovering but died following interruption of the artificial respiration.

Some of the deaths were associated with delay in administering a part of the treatment, and it is probable that a somewhat higher percentage of recoveries would

Artificial respiration does not prevent the peripheral muscular paralysis that ordinarily follows fatal doses of nicotine and it has to be continued until this passes away. The duration of the paralysis varied a great deal (from ten minutes to three hours and twenty minutes) and was not always proportional to the dose of nicotine. For example, one animal that had been given 10 mg

TABLE 1—Results with Artificial Respiration as the Only Therapeutic Measure

have been obtained if the treatment had been started promptly in all the animals. However, a few animals died which were given the full treatment as soon as possible after the failure of the circulation and respiration had been established.

Most of the failures were in animals in which the symptoms developed slowly and a comparatively long period of partial asphyxia preceded the beginning of treatment.

per kilogram intravenously recovered completely after ten minutes of artificial respiration, while another animal treated in the same way, after 5 mg per kilogram took one hour and fifteen minutes to recover. Because of the extreme variability in the duration of the paralysis it is not possible to determine accurately whether it was influenced by the different procedures, but it appears to be about the same in this group as in the preceding.

A constant tendency toward a fall in body temperature was noted during the period of paralysis. A rectal temperature of 31.5 C (88.7 F) was observed in one animal that did not recover. Although we applied heat in only a few experiments, its use is evidently indicated in prolonged muscular paralysis.

Two deaths were reported among the seventeen animals that recovered from the acute effects of the poison and were allowed to live. One of these was a pregnant bitch that died seventeen days after the experiment. The cause of death was not determined. The other animal had a respiratory infection that was evident on

In nine of a group of sixteen animals the heart beat was restored by means of artificial respiration and direct cardiac massage without epinephrine. In six animals the procedure failed to restore the circulation and epinephrine was tried later. In one the heart began to fibrillate before epinephrine could be used. This one experiment and the nine successful experiments of this group are listed in table 3. The six that were finally given epinephrine are listed in table 4 with the other experiments in which epinephrine was used.

Artificial respiration, direct cardiac massage and intracardiac epinephrine were tried in ten animals,

TABLE 3—Results with Artificial Respiration and Direct Cardiac Massage Without Epinephrine

the day of the experiment and became very much worse the following day. The other animals were apparently normal on the day following the experiment and continued so indefinitely.

C Artificial Respiration and Direct Cardiac Massage, With or Without Epinephrine—Although direct cardiac massage is rarely a practicable procedure outside the laboratory, these experiments are thought to be worth reporting for the light they throw on the ability of the circulatory mechanism to recover following failure induced by nicotine.

In all these animals the thorax was opened excluding the possibility of dispensing with the artificial respiration, so that only the circulatory phenomena are of interest. All the animals were killed at the end of the period of observation.

including the six in which a previous attempt at resuscitation without epinephrine had failed. In five of these the heart beat was restored and continued till the end of the experiment.

In the other five the heart either fibrillated or failed entirely to respond to the treatment. In three of these a prolonged attempt to restore the heart's action without epinephrine had failed and epinephrine was used as a last resort. In the other two the treatment was applied as promptly as in many that recovered, and these must be regarded as instances in which the method of resuscitation failed even when administered satisfactorily. Further details of these experiments are given in table 4.

All together direct cardiac massage was used, with other treatment in twenty animals after the circulation

had failed following the administration of nicotine. Resuscitation failed in a total of six of the twenty trials but in only three that cannot be accounted for by unusually unfavorable conditions. This is probably as good a record as could be obtained in a similar number of cases of simple asphyxia.

COMMENT

The use of artificial respiration to keep animals alive after the administration of what would otherwise be a fatal dose of nicotine is a common laboratory procedure. It was used by Langley and Dickinson¹² on the rabbit, cat and dog. It would seem that this fact should have suggested this measure as a means of treatment of acute poisoning in the human being. However, artificial respiration is seldom mentioned in this connection. We know of but three cases in which it has been tried. In one instance the patient recovered and in the other two life was evidently prolonged.

Hatcher¹³ noted that artificial heat caused a marked improvement in the condition of rabbits that had been injected with nicotine hypodermically.

Gautrelet and Halpern¹⁴ report an antagonism between nicotine and iodomethylate of methenamine. Their observations were made on experimental animals.

Our results indicate that artificial respiration started before the circulation has failed and continued until the muscular paralysis passes off should prove uniformly successful. They indicate also that there may be considerable hope of restoring the circulation soon after it has failed by injection of epinephrine into the left ventricle and indirect massage of the heart through the chest wall. Direct cardiac massage is not often a practical procedure in man, but the fact that it proves successful in a considerable percentage of cases in animals indicates that the nervous elements necessary for the maintenance of the circulation are not necessarily paralyzed by the action of nicotine.

Nicotine poisoning is relatively rare, but it is a potential menace in tobacco factories, especially those which manufacture nicotine products. All such places should be provided with means for the prolonged administration of artificial respiration and employ some one trained in its use. Artificial respiration should also be mentioned in the directions for the treatment of poisoning given on the labels of containers for nicotine.

SUMMARY

Various means of treatment and resuscitation were tried in fifty-two dogs acutely poisoned with nicotine.

Artificial respiration was uniformly successful if it was started before the circulation had failed and was continued till the muscular paralysis had disappeared.

Artificial respiration, intracardiac injection of epinephrine and indirect cardiac massage were used with fair success to resuscitate animals in which the circulation and respiration had failed.

The circulatory failure that follows fatal doses of nicotine in dogs is not necessarily permanent but is recovered from promptly if the heart can be started and artificial respiration maintained.

Prolonged artificial respiration and when the heart has stopped, intracardiac injection of epinephrine are recommended for trial in cases of acute nicotine poisoning.

HYPERSENSITIVENESS TO PITUITARY EXTRACTS

FRANK A. SIMON, M.D.

AND

C. F. RYDER, M.D.

LOUISVILLE, KY.

Hypersensitiveness to pituitary extract is apparently an uncommon condition. Hasson¹ in 1930 reported a case of general reaction following the injection of pituitary extract, and Wang and Maxwell² in 1933 reported a similar case of shock which occurred post partum and which they proved, by reinjecting a smaller quantity of the drug, to be due to solution of posterior pituitary. In neither of these cases is there a record of skin tests or of other allergic studies. One of us recently described a case which is presented here with four others that came to our attention later. Personal inquiry³ has revealed six other cases of general reaction in which posterior pituitary extract was suspected as the etiologic factor.

In a period of less than two years five cases of hypersensitiveness to pituitary extract have been observed in the Louisville City Hospital, three of the cases occurring within three months.

CASE 1—Mrs. H. F., an American housewife, aged 28, in good general health, the mother of seven children, had no personal or family history of allergic diseases. Following the birth of two of her first five children she was given a subcutaneous injection by her private physician (presumably pituitary extract). In November 1933 she was given the usual injections of pituitary extract and ergot following the birth of her sixth child. There were no untoward reactions from any of these injections. Her seventh baby was born Nov. 8, 1934, and again the usual subcutaneous injections of pituitary and ergot were given. About thirty minutes later massive swelling of the lips and face was noted and the patient complained that her tongue felt as if it were greatly swollen. She began to have respiratory difficulty which increased steadily until it was relieved by epinephrine. She recovered completely and had an uneventful puerperium until the sixth day post partum at which time a generalized urticarial rash occurred with considerable itching and discomfort. This lasted five days, gradually subsiding and leaving the patient feeling well. Apparently the patient was sensitized by one of her previous injections, namely that of November 1933.

CASE 2—C. R., aged 26, the mother of five children, without a personal or family history of allergy received pituitary extract post partum on Oct. 7, 1929, Sept. 8, 1932, and Feb. 4, 1934. There were no unusual symptoms from any of these injections. On Dec. 5, 1934, she was given double strength pituitary extract twelve doses, 0.5 cc. each, following a dilation and curettage for hyperplastic endometritis. There were no immediate reactions, but six days later she began to have swelling of the face and hands and a generalized urticaria developed which lasted five days. She was apparently sensitized by the injections given on Dec. 5, 1934.

CASE 3—M. J., aged 35, without personal or family history of allergy has two children aged 2 and 10 years, respectively. She received pituitary extract after both deliveries and no unusual reactions were noted. On Feb. 3, 1935, she was given 1 cc. of double strength pituitary extract for relief of abdominal distention. Three hours later she noticed a firm swelling at the site of injection in the thigh. The following day this swelling had increased considerably and was described as being the size of a dinner plate. No urticaria or other general symptoms were noted. This patient was apparently sensitized by

a previous injection, but as will be seen later (table 2) the degree of sensitization in this case is less than in cases 1 and 2.

CASE 4—G W, aged 32, has a history of nine pregnancies and of a subcutaneous injection (presumably pituitary extract) after each delivery. Her mother has severe asthma and the patient is clinically sensitive to egg. She vomits and has smothering spells whenever she eats even a small quantity of egg. She often has attacks of urticaria. April 12, 1933, she was given pituitary extract following the birth of her tenth child. Within thirty minutes there was a marked swelling of the tongue and throat, a rash over the entire body, and considerable respiratory difficulty. Epinephrine was administered and four hours later she felt quite comfortable but still had some swelling of the tongue and throat.

CASE 5—M C, aged 36, has had ten children and four miscarriages. She has had an itching eruption for the past twelve to fifteen years, which is made worse by eating tomatoes. During the birth of four or five of her children she was given, by her private physician, injections to hasten the delivery (pre-

neous material added in the manufacturing process. All tests were done in duplicate and all substances giving positive reactions were applied in the same way to a normal person with negative results.

It is apparent from table 4 that these patients are sensitized to some constituent of the pituitary gland and not to a preservative or other foreign material. It is apparent also that the specificity is not directed toward some species specific factor distributed throughout the various tissues of some particular species of animal or toward the brain tissue of one or more animal species. It is directed, at least in part, toward some constituent of the pituitary gland of several animal species, including man himself. The question arises: Is this constituent a recognized hormone or some other substance present in the gland? The hormones of the pituitary gland, so far as their pharmacologic

TABLE 1—Summary of Cases

* Presumably

sumably pituitary extract). No abnormal reactions were noted after any of these injections. Her ninth baby was born in the hospital on March 18, 1933. Pituitary extract and ergot were given after delivery and shortly after the injections (a few minutes according to the patient's history, an hour and a half according to the hospital records) she became nauseated, vomited, 'got red all over,' and had swelling of the tongue, face and hands and considerable difficulty in breathing. Epinephrine was given and an hour later she was much improved. The remainder of the puerperium was uneventful. Her tenth child was born April 9, 1935, but no pituitary was given.

These cases are summarized in table 1.

Skin tests were made on these five patients with various preparations. The results are shown in table 2, from which it may be seen that sensitization is not limited to one particular brand of extract, for positive tests were obtained with five different brands comprising extracts of both the anterior and the posterior lobes. Pitocin, containing the oxytocic factor, gave negative tests, while pitressin, containing the vasoconstrictor and antidiuretic principles, gave positive tests. The controls, ergot and physiologic solution of sodium chloride, were negative. All these extracts gave negative tests on a normal control subject.

The results of a titration of the skin sensitivity by skin tests with serial dilutions in the five cases is shown in table 3. Evidently these patients have a high degree of skin sensitivity comparable to that seen in hay fever. The first two patients are more highly sensitive than the remaining three.

The skin tests recorded in table 4 were made in an effort to identify the constituent in the extract to which these patients are sensitized. Emulsions of fresh material were used in these tests in order to exclude the influence of preservatives and other possible extra-

action is concerned, are known to be organ specific rather than species specific. The possibility exists, however, that some other constituent of the gland is likewise organ specific. The hormone of the posterior pituitary has not been synthesized or even isolated in crystalline form, but relatively pure preparations have been made, and the vasopressor and oxytocic factors have been separated by Kamm and his associates.⁵

Physiologic solution of sodium chloride	—	—	—	—	—

Through the courtesy of Dr. Kamm we obtained special purified preparations of pitressin containing 10 pressor units, 0.4 oxytocic unit and 0.23 mg total solids per cubic centimeter, and of pitocin containing 10 oxytocic units, 0.2 pressor unit and 0.034 mg total solids per cubic centimeter. Skin tests were made with serial dilutions of these preparations and also with commercial pituitary extract (obstetric), which contains 10 units of both pressor and oxytocic principles and from 5 to

⁵ Kamm, Oliver, Aldrick, T. B., Grote, I. W., Rowe, L. W., and Bugbee, E. P., The Active Principles of the Posterior Lobe of the Pituitary Gland, *J. Am. Chem. Soc.* 50: 573, 1928.

10 mg total solids per cubic centimeter. All five patients reacted in a similar manner to these tests. Table 5 shows a typical result in one case and also the result in a nonsensitive control subject.

From table 5 it may be seen that in the three preparations of posterior pituitary the capacity to give skin reactions in a sensitized patient is not proportional to the degree of pharmacologic activity but is more nearly proportional to the total solids. It is possible to separate, to a great extent, pharmacologic activity from capacity to give skin tests. Hence the sensitivity is not due to the vasopressor or oxytocic factors but to some other constituent of the gland.

The hormones of the anterior pituitary have neither been synthesized nor prepared and standardized in sufficiently pure form to be of much value in differential skin testing. From table 2 it may be seen that positive skin tests were obtained with three different preparations of the anterior lobe and negative skin tests with one preparation. Negative tests were also obtained with the anterior pituitary-like hormone obtained from pregnancy urine (Antuitrin-S).

Skin tests were made by the scratch method on the youngest babies of patients 1, 4 and 5 thirteen days, twenty-three months and six days respectively, after

birth. These tests were entirely negative to the same pituitary extracts used in testing the mothers. The ninth child of patient 5 also gave a negative test twenty-five months after birth.

Local passive transfer (Prausnitz-Kustner) was strongly positive with the serum of patient 1 (H F) on Nov 21, 1934, thirteen days after the last injection of pituitary extract. Two recipients were used and the reaction was easily elicited both by the scratch method and by the intradermal method. The controls were

negative. Commercial pituitary extract, 1:10 dilution was used as the test substance. March 20, 1935, four months later, local passive transfer was attempted again on three recipients. Both commercial and human pituitary extracts were used as test substances. The tests were negative to both extracts in all three cases. The same test substances, however, gave strongly positive skin tests on the patient herself at the time the blood

was taken for transfer. The skin tests remained strongly positive but reagins could no longer be demonstrated in the blood. This result is similar to that described by Tuft in a case of insulin sensitivity.⁶

March 4, 1935, local passive transfer was attempted in four recipients with the serum of cases 2 and 3 three months and one month, respectively, after the last pituitary injections. There was no transfer in any case. There was likewise no transfer in two recipients with the serum of the fourth patient which was taken April 4, 1935, two years after the last injection of pituitary extract. But in the fifth case local passive transfer was definitely positive to commercial pituitary extract in two recipients on April 15, 1935, more than two years after the last injection of pituitary. No transfer could be demonstrated, however, with our preparation of human pituitary extract, to which the patient herself was only slightly sensitive and which was weaker than the commercial preparation, as shown by the fact that its intradermal injection in normal persons produced very little blanching of the skin.

Commercial pituitary extract in pharmacologic doses is not a good antigen either for the guinea-pig or for man under ordinary conditions. Five guinea-pigs were given intradermal injections of the extract (obstetric, 0.2 cc) and tested after four days, nine days and three weeks by intradermal injection. The skin reactions in these animals were no different from those of the controls at any time. Thirty primiparas were tested with

6 Tuft, Louis. Insulin Hypersensitiveness. Immunologic Considerations and Case Reports. *Am J M Sc* 176:707 (Nov) 1928.

7 The blanching effect of the vasopressor hormone interferes to a certain extent with the interpretation of skin tests in the guinea pig hence a slightly positive reaction might be unapparent.

pituitary extract, obstetric, 1:10 dilution, by scratch and intradermal methods at two different times, namely, at the time of delivery when they received a postpartum injection of pituitary and nine days later before they left the hospital. In sixteen of these cases additional skin tests were made about six weeks later at the postpartum clinic. A diagrammatic record of the skin reactions was kept in each case so that comparisons could be made between the first and second or the first and third reactions in any one patient. Such comparisons were made but no evidence of sensitization was found in any case. Apparently special conditions are necessary for the development of hypersensitivity to pituitary extract in man.

COMMENT

Hypersensitivity to pituitary extract seems to be uncommon. However, the occurrence of five cases in one hospital in less than two years suggests the possibility that some cases have been unrecognized and others unreported. Pituitary preparations are used extensively in the practice of medicine especially in obstetrics and it seems that this condition would be worth keeping in mind in cases of obscure reactions following delivery when pituitary extract has been used.

This hypersensitivity cannot be produced at will but occurs only in exceptional cases under conditions that are unknown at the present time. It is not merely a matter of certain individuals being predisposed while others are not. The predisposition, even in susceptible persons, is not always present. This is apparent from the fact that these patients had previous injections of pituitary extract which were without effect in producing hypersensitivity. This predisposition then is apparently present only in certain individuals at certain times. The analogy with hay fever is at once apparent. Only a relatively small percentage of those who are exposed become sensitized, and of those who do become sensitized many were exposed ineffectively for years before sensitization developed. The persistent, high degree of sensitivity, the presence of reagins and the family or personal history of allergy in two of the patients constitute further evidence that these are not cases of the ordinary anaphylactic type of hypersensitivity such as may be produced at will in laboratory animals and in man by the injection of a foreign serum.⁸

The absence of positive skin tests in four children born of three sensitized mothers with positive skin tests constitutes evidence against the idea of transplacental transmission of hypersensitivity.

These cases undoubtedly represent organ specificity rather than species specificity, the specificity being directed toward some constituent of the pituitary gland of several animal species, including man.

SUMMARY

1. Hypersensitivity to pituitary extract occurs in only a small percentage of exposed persons.

2. Skin tests with various substances indicate that this is an organ specific hypersensitivity directed toward some constituent of the pituitary gland of several animal species including man.

3. This constituent is neither the vasopressor nor the oxytocic principle of the posterior pituitary.

MENSTRUAL EDEMA

THE REPORT OF A CASE CONTROLLED BY ENEMENIN
BUT NOT BY THECLOL OR THFELIN

ARTHUR J. ATKINSON, M.D.

AND

ANDREW C. IVY, Ph.D., M.D.

CHICAGO

Thomas¹ has reported two cases in which edema occurred regularly and only during menstruation. One of these patients was given hypodermic injections of anterior pituitary extract and later the gonadotropic substance of pregnancy urine. With the latter therapy he was able to prevent the edema. Sweeney² reported observations on the body weight of forty-two normal healthy young women. Thirty per cent showed a gain of 3 or more pounds sometime during the menstrual

cycle, usually just before the menstrual flow was established. Some had a true pitting edema. Okey and Stewart³ have also followed the weight of twenty women students and found an increase in weight of from 1 to 3 pounds (453 to 1360 Gm.) in one fourth of their subjects. Almost all the students who showed the gain in weight gave histories of menstrual headaches or discomfort. Eufinger and Spiegler⁴ observed a tendency to edema in 47 per cent of their subjects.

We have had the opportunity of observing a patient with pronounced menstrual edema of long standing in which certain blood chemical studies have been made and the condition prevented by the administration of

emmenin (Collip) but not by theelol and theelin. The study has extended over a period of more than one year. The more pertinent points are briefly as follows:

History.—The patient is now 47 years of age and unmarried. Since the onset of menstruation at the age of 13 years the menses have been complicated by a swelling of the feet and legs. The feet would begin to swell about one week before menstruation and the swelling did not recede until a week after the cessation of the flow. The swelling would pit on pressure. During the past five years the edema has been worse than it had been previously, and considerably more marked

during the past year with some edema constantly present. The edema showed diurnal variation, being greater at bedtime. Frontal headaches, epistaxis and herpes simplex usually have accompanied the edema. Menopausal symptoms have not appeared and the periods have been regular, occurring in a twenty-six to thirty day cycle and lasting four days. The body temperature and blood cells were normal. The bleeding time was normal. The blood pressure was 138 systolic, 88 diastolic. There were no casts and no albumin in the urine. The basal metabolic rate was minus 19. The blood proteins were normal and showed no appreciable variation during a complete menstrual cycle. The individual determinations at weekly intervals were 8.52, 9.1, 9.25 and 8.6 Gm per hundred cubic centimeters. Roentgen study of the sella turcica revealed no abnormality.

Preliminary Therapeutic Tests.—Desiccated thyroid (0.12 Gm daily) was administered. The basal metabolic rate was elevated to normal, but the edema was not influenced. The degree of edema was followed daily throughout the study by measuring the water displacement of the feet. The edema was not influenced by ammonium nitrate, potassium chloride, calcium gluconate or vitamin therapy.

Blood Lipid Studies.—It was decided to study the blood lipids during the menstrual cycle in this patient both before and after endocrine therapy.

This was considered important because of the observations of Okey and Boyden⁵ and others.⁴ Okey and Boyden found that blood cholesterol decreased almost invariably during or just prior to the onset of the menses. This decrease was usually preceded or followed by a rise in blood cholesterol above the normal average. This was confirmed by Kaufmann and Muhlbock,⁶ who further stated that in patients with ovarian dis-

turbances the rhythmic variation in blood cholesterol did not occur. Okey³ noted in addition that Dahlmö and Solé⁷ and Degkwitz⁸ had suggested that cholesterol acts in the blood as a lyophobic colloid, while lecithin acts a lyophilic colloid. Therefore Okey, observing variations in the cholesterol-lecithin ratio in blood during the menstrual period, has intimated that this may be the cause of the edema, i. e., that a low cholesterol and a relatively high lecithin content may cause the tissues to imbibe water.

We have determined the total and free cholesterol and the total fatty acids at five day intervals in this patient over a period of six months. During a portion of this period no therapy was given at other times gonadotropic principle from pregnancy urine and emmenin⁹ were given.

Without treatment a regular premenstrual fall in blood cholesterol did not occur (table 1). According to Kaufmann and Muhlbock⁶ this would indicate an ovarian dysfunction.

Pregnancy-urine extract (12,000 rat units) was then given during a period of two months. A reduction in the amount of edema resulted. On withdrawal the edema returned. It was then given again, but with little effect on the edema, and finally was discontinued because it apparently had produced metrorrhagia. The blood cholesterol and total fatty acids were not significantly altered (table 1).

Administration of Emmenin (ether insoluble complex from placenta, relatively inert in ovariectomized rats but estrogenically active in the presence of immature or atrophic ovaries).—The administration of emmenin (12 cc daily, 60 day oral units-Collip) resulted in a complete disappearance of the edema including that which persisted between periods (table 1). When the emmenin was withdrawn, the edema reappeared with the next menstrual cycle. While the patient was taking emmenin there was no significant change in the basal metabolic rate.

(—175) and the menstrual headaches did not occur. A significant change in the blood lipids was not observed during the period of study (tables 1 and 3).

Administration of Theelin.—Collip, Browne and Thomson¹⁰ regard emmenin as a hydrolyzable compound of trihydroxy-estrin (theelol), the active principle of which is converted to some more potent substance in the presence of ovarian tissue. Theelol is liberated from emmenin by autoclaving with acetic acid. Although theelol, like emmenin, is active by mouth the difference in the solubility of the two may render possible physiologic differentiation in activity, or more probably

emmenin may contain an unknown substance in addition to the estrin complex. Except for these possibilities theolol, in doses of equal estrogenic potency, should be effective. To test this possibility theolol was given the patient.

Theolol (150 rat units) was given daily for one month. The edema was not influenced (table 2).

Administration of Theelin.—Because emmenin has a powerful estrogenic potency when given orally, it was decided to ascertain if theelin hypodermically would prevent the edema. Theelin (600 rat units every alternate day) was given for two and one-half weeks. In the doses used it had no effect on the edema (table 2). One might not expect such doses to have an effect because it has been stated that very large doses (65 000 rat units)¹¹ are required to produce a definite effect in women.

Following the trial with theolol and theelin emmenin again had a beneficial effect (table 3).

Two other patients with a similar history of premenstrual edema have been given emmenin with subsidence of the swelling.

SUMMARY

Certain therapeutic procedures administered with the object of preventing edema failed with the exception of the administration of the gonadotropic principle from pregnancy urine, which was slightly effective, and emmenin (Collip), which was markedly effective. The blood lipids, which varied considerably, were followed for more than ten months in one patient and were not significantly or strikingly influenced.

55 East Washington Street—303 East Chicago Avenue

THE FREI TEST FOR LYMPHO-GRANULOMA INGUINALE

EXPERIENCES WITH ANTIGENS MADE FROM MOUSE BRAIN

MAURICE J. STRAUSS, MD

AND

MARION E. HOWARD, MD

NEW HAVEN, CONN.

Since Frei¹ demonstrated that an antigen, made from sterile pus aspirated from previously unruptured abscesses, produced a reaction in patients with lymphogranuloma inguinale when injected intradermally, many attempts have been made to find other reliable sources for this antigen. Satisfactory antigens have been made by grinding up infected glands and periglandular tissues, and there have been reports of antigens made from pus from rectal fistulas occurring in patients with the late manifestations of this disease. This reaction is an important aid in the diagnosis of lymphogranuloma inguinale.

It is now well known that mice can be infected with lymphogranuloma inguinale by intracerebral inoculation of material from early cases and that the infection can be passed through several generations. One of the means of determining whether an animal has been infected with the disease is by making an antigen from the brain tissue and testing this on patients known to have the disease. Grace and Suskind² state that "evidence of the presence of the virus of lymphogranuloma inguinale in the brains of the dead mice was furnished by the production of highly potent Frei antigens from these brains and also that normal mouse brains prepared and tested as Frei antigens do not produce any

appreciable reactions." An antigen made from infected mouse brain has recently been produced and sold for the diagnosis of lymphogranuloma inguinale.

We have been interested in transmitting this disease to mice and in testing antigens made from mouse brain and have noted that such antigens when freshly prepared and injected into the skin of normal controls have regularly produced a small erythematous papule about 2 mm in diameter.

EXPERIMENT 1.—In order to see whether the antigen prepared from mouse brain and sold commercially produced a similar reaction in normal persons the following experiment was per-

Fig. 1 (subject M. I. S.)—Results in experiment 1. The numbers correspond to the numbers of the antigens as given in the text.

formed. We were used as normal subjects and the following substances were injected intradermally: (1) a tested Frei antigen made from pus from an inguinal abscess; (2) an antigen made five months before from the brain of a mouse infected with lymphogranuloma inguinale; (3) an antigen made five and one-half months before from the brain of a normal mouse; and (4) the commercial Frei antigen. At the end of forty-eight hours there was no reaction at the site of injection of the antigen made from pus but at the site of each of the other injections there was seen a dome-shaped papule from 5 to 7 mm in diameter with a surrounding erythematous area about 15 cm in diameter.

It was apparent that all these reactions were more marked than had been seen before in normal subjects. That the subjects did not have lymphogranuloma inguinale was clearly shown in two ways: (1) the negative reaction to a potent Frei antigen made from human material and (2) the fact that an antigen made from the brain of a normal mouse gave the same reaction as one from the brain of an infected mouse. The only difference between our previous experiments and the present one was that the material injected in this experiment was five months or more old and previously antigens had been tested as soon after their preparation as possible. Accordingly an antigen was freshly prepared from the brain of a normal mouse and injected intradermally at the same time as the old antigen from normal mouse brain that had been used before. There was a marked difference in the results, the freshly prepared antigen producing a papule only 2 mm in diameter and the old antigen a papule 6 mm in diameter.

11 Kaufmann C. *Zentralbl f Gynak* 57:42 (Jan 7) 1935.
From the Department of Internal Medicine and the Division of Dermatology, Yale University School of Medicine.
1 Frei Wilhelm. *Klin Wochenschr* 4:2148 (Nov 5) 1925.
2 Grace A. W. and Suskind I. H. *Proc Soc Exper Biol & Med* 22:1 (Oct) 1934.

3 The antigen was prepared by grinding the brain of one mouse under aseptic precautions with a mortar and pestle and without any abrasive until a smooth paste was obtained. To this paste 4 cc of Savin broth was added drop by drop with constant grinding. This mixture was then sealed in tubes and inactivated in the water bath at 60 C for two hours the first day and one hour the second day.

It seemed therefore that some change had taken place over a period of five months in the antigen made from normal mouse brain so that on intradermal injection into normal subjects a reaction similar in appearance to a positive Frei reaction was induced.

EXPERIMENT 2—The following materials were injected intradermally in the same subjects and, in addition, in a patient in the wards of the New Haven Hospital who showed no evidence of having or having had lymphogranuloma inguinale.

Fig 2 (subject M J S)—Results in experiment 2. The numbers correspond to the numbers of the antigens as given in the text.

(1) a tested Frei antigen made from pus from an inguinal abscess, (2) an antigen made seven months before from the brains of mice infected with lymphogranuloma inguinale, (3) an antigen made seven and one-half months before from the brain of a normal mouse, (4) the commercial Frei antigen, (5) an antigen made four weeks before from the brain of a normal mouse, and (6) the same antigen, which had been dried in vacuo⁴ immediately on preparation and prepared for injection on the day of the experiment.

10 Commercial Frei antigen	4	5		Not done	Not done	

Since the results in all three subjects were closely parallel they will be given in detail for only one subject (M J S). To antigen 1 there was no reaction, to 2 there was a papule 4 mm in diameter with a surrounding erythema 10 mm in diameter, to 3 a papule 5 mm in diameter with a surrounding erythema 12 mm in diameter, to 4 a papule 7 mm in diameter with a surrounding erythema 14 mm in diameter, to 5 a papule 6 mm in diameter with a surrounding erythema 14 mm in diameter and to 6 a papule 3 mm in diameter with no appreciable surrounding erythema.

⁴ The antigen was prepared from the brain of a normal mouse and dried in vacuo in the frozen state the Mudd-Flossdorf apparatus being used. It was prepared for use subsequently by making it up to the original volume with saline solution.

Again the antigen made from pus gave entirely negative results. The other antigens made from mouse brain gave appreciable reactions with some minor variations between the individual antigens, and it was noteworthy that an antigen prepared only one month before had already developed the ability to induce positive reactions. The same mouse brain antigen that had been preserved in the dried state had not. The remainder of this antigen was kept in the icebox for one month for a further experiment.

EXPERIMENT 3—The two original subjects were used with the addition of two patients in the early active stages of lymphogranuloma inguinale. The antigens used were as follows:

(1) lymphogranuloma mouse brain prepared more than eight months before, (2) normal mouse brain prepared more than eight months before, (3) normal mouse brain prepared two months before, (4) the same mouse brain dried two months before and prepared for injection one month before, (5) the same mouse brain dried two months before and prepared for injection on the day of the experiment, (6) normal mouse brain prepared the day before the experiment saline solution being used instead of broth, (7) normal mouse brain prepared with broth the day before the experiment, (8) lymphogranuloma mouse brain prepared the day before the experiment, (9) a tested Frei antigen made from excised glands from one of the patients used in the experiment and (10) the commercial Frei antigen (used in the two normals only). The size of the resulting papules appears in table 1.

With a total of thirty-eight intradermal injections, it was not surprising that a few discrepancies appeared. At the time of injection it was suspected that antigen 2 in the case of M E H was injected almost entirely hypodermically instead of intradermally. We cannot explain other discrepancies such as the failure to react of antigen 4 in M J S and antigen 7 in M E H and the unusually strong reaction of N S to antigen 3. In spite of these discrepancies a few facts were evident. It was clear that the two normal subjects had not been infected with lymphogranuloma inguinale, as shown by the absence of reaction to antigen 9. The

Fig 3 (subject M J S)—Results in experiment 3. The numbers correspond to the numbers of the antigens in table 1.

results with all the mouse brain antigens showed that, regardless of whether or not the mice had been infected with lymphogranuloma inguinale, an antigen made from mouse brain was capable of producing an appreciable reaction when injected intradermally.

The reactions induced by antigen 4 seem to indicate that the change which takes place in mouse brain antigens causing these false reactions may take place within two months even if the antigen is preserved in the dried

state Comparisons of the papules induced by antigens 6 and 7 make it appear that at the time of preparation there was no marked difference between an antigen prepared with saline solution and one prepared with broth

EXPERIMENT 4—Although the normal subjects used in these experiments showed a marked reaction to antigens made from mouse brain from the first, it was possible that the succeeding reactions were due to an acquired sensitivity to mouse brain. To rule this out, various antigens were injected intradermally into six subjects in whom there was neither history nor evidence of lymphogranuloma inguinale and who had never had injections of any material made from mouse brain. The same antigens were injected into three patients with lymphogranuloma inguinale and in one questionable case. The following antigens were used: (1) a Frei antigen made from pus, (2) a Frei antigen made from excised glands removed from one of the patients used in the experiments, (3) lymphogranuloma mouse brain prepared more than nine months before, (4) lymphogranuloma mouse brain prepared one month before, (5) the commercial Frei antigen, (6) normal mouse brain prepared more than nine months before, (7) normal mouse brain prepared more than three months before, (8) normal mouse brain prepared with saline solution instead of broth approximately two months before, (9) normal mouse brain prepared with

sensitivity of different subjects would explain the two weak reactions to one of the Frei antigens in two of the normal subjects (H H and M M). It was impossible to draw the conclusion that these two subjects had lymphogranuloma inguinale, as in each case the reaction was considerably less than that considered as a typically positive Frei test, and in each case the subject failed to react at all to another Frei antigen.

That mouse brain is capable of inducing in normal subjects a reaction sufficiently marked to be mistaken for a Frei reaction was evident from an analysis of the results. Forty-eight injections of mouse brain were made in the normal controls. In twenty-one, or 43.8 per cent, the reactions were 6 mm or more in diameter and indistinguishable from positive Frei reactions. In seventeen, or 35 per cent, they were from 4 to 5 mm in diameter or easily mistakable for positive Frei reactions. In the group of patients having lymphogranuloma inguinale we could only consider in the same manner the injections of normal mouse brain. There were twenty such injections. With the same criteria as before, three of these, or 15 per cent, were indistinguishable from positive Frei tests, but fifteen, or 75 per

TABLE 2—Results in Experiment 4

broth the day before the experiment, and (10) normal mouse brain prepared with saline solution the day before the experiment. The results appear in table 2.

It should be noted that F McV was not included in the group of patients having lymphogranuloma inguinale because many tests in this patient with Frei antigens made from human material have resulted in papules that were smaller than those generally considered positive tests. This patient was a young white woman in whose history and physical examination there was nothing suggestive of lymphogranuloma inguinale. She was referred for Frei tests because of an unhealed ulceration over the sacrum which followed the surgical removal of a pilonidal cyst. As can be seen from table 2 the difference between the size of the papules resulting from intradermal injections in this patient and in patients with typical lymphogranuloma inguinale was greater with Frei antigens made from human material than with antigens made from the brains of mice inoculated with lymphogranuloma inguinale.

The group of patients could be definitely differentiated from the group of normal subjects by the reaction to the two antigens (1 and 2) made from human material. Throughout the experiments it was quite evident that there was considerable variation both in the antigenic properties of the materials injected and in the sensitivity of different subjects. The individual

cent, were easily mistakable for positive Frei tests. It was also noted that of twenty injections of lymphogranulomatous material made either from mouse brain or from human material in this group, nine, or almost one-half the reactions, were less than 6 mm in diameter.

That intradermal injection of mouse brain in patients known to have lymphogranuloma inguinale is a valuable method for determining whether the mouse has been infected with lymphogranuloma inguinale is evident from a comparison of the papules resulting from such injections with those resulting from the injection of material from normal mice. In table 2 it can be seen that in isolated instances the injection of normal mouse brain in the three patients with typical lymphogranuloma inguinale induced a reaction easily mistakable for a true Frei reaction. The majority of these injections resulted in the formation of a papule less than 6 mm in diameter. Injection in the same patients of antigens made from the brains of mice that had been inoculated with the disease resulted with few exceptions in larger papules. In these patients the papules induced by lymphogranuloma mouse brain averaged 6.22 mm in diameter and those induced by normal mouse brain averaged 4.4 mm. Comparison of the results in these three patients with the results in the questionable diagnostic case shows that there was an appreciable difference when lymphogranuloma mouse

brain was used, the three antigens giving rise to papules averaging 4.33 mm against 6.22 mm in the known cases

COMMENT

The circular that accompanies the Frei antigen sold commercially gives as the criterion of a positive Frei reaction "an erythematous papule not less than six millimeters in diameter surrounded by a less erythematous zone of varying size." It must be admitted that the size of a papule does not lend itself to exact measurement and for this reason it is quite conceivable that a papule 5 or even 4 mm in diameter might frequently be read as a positive test. The experiments cited show that, irrespective of whether the mouse had been infected with lymphogranuloma inguinale or not, an antigen made from the brain of a mouse may induce a reaction similar to the Frei reaction when injected intradermally. In this series of experiments nearly half the reactions to mouse brain antigens injected intradermally into normal subjects were of such a nature as to make them indistinguishable from what is recognized as a positive Frei test, and some of the reactions were of such size and character as to make them easily mistakable for positive Frei reactions.

False reactions may result from freshly prepared mouse brain antigen but in our experience are to be watched for when using material that has been stored a month or more. The indications are also that preparation of the antigens with saline solution instead of broth does not influence the reaction. It would seem from experiment 2 that if the antigen is preserved in the dried state the appearance of the false reaction may be prevented for a period of one month although

Fig. 4 (subject N. D. E.)—Results in experiment 4. The numbers correspond to the numbers of the antigens in table 2.

the results of the third experiment make it seem that in some antigens at least the change may take place even in the dried state by the end of two months.

The regularity with which tested Frei antigens made from human material were negative is conclusive proof that the normal subjects did not have lymphogranuloma inguinale, and even if the total number of subjects was small being only thirteen the fact that definite reactions to antigens made from the brains of normal mice occurred in all of them and reactions indistinguishable from positive Frei tests in many instances justifies the conclusion that sensitivity to mouse brain is common enough to lead to a large number of false positive reactions if mouse brain antigens are used for the diagnosis of lymphogranuloma inguinale.

CONCLUSIONS

- 1 Some change occurs in antigens made from mouse brain within a few weeks after preparation which, when injected intradermally, gives rise to a reaction almost indistinguishable from a true positive reaction.
 - 2 The nature of this change is at present unknown.
 - 3 This occurs in antigens made from the brains of normal mice as well as in antigens made from the brains of mice inoculated with lymphogranuloma inguinale.
 - 4 The false reaction is induced in normal subjects as well as in patients with lymphogranuloma inguinale.
 - 5 For this reason Frei antigens made from mouse brain would not appear to be suitable for the routine diagnosis of lymphogranuloma inguinale.

AUTOTRANSFUSION IN THE TREATMENT OF WOUNDS OF THE HEART

CHARLES M. WATSON, M.D.
AND
JAMES R. WATSON, M.D.
PITTSBURGH

Penetrating wounds of the heart usually are rapidly fatal. In spite of the fact that the infrequency of the condition prevents any one man from acquiring a wide experience, analysis of reports collected from the literature, as well as facts obtained from animal experimentation, have established methods which are proving their value in the increased number of successful cases that have been reported in the last few years. This is verified by the periodic reviews of the literature, which have shown a decline in the mortality rate from 63.7 per cent, as reported by Peck¹ in 1909 to 34 per cent as reported by Ramsdell² in 1934, given in the accompanying table. It is our desire to call attention to a procedure which, if used more frequently in certain types of injury, may possibly result in a further reduction in the mortality rate. Descriptions of the various surgical approaches, as well as the technic of cardiorrhaphy, need not be included here, for they may be found in many articles on the subject notably those by Beck³ and Cutler⁴.

Hemorrhage is the most common cause of death in the group in which the patient lingers sufficiently long to reach the hospital, whether it is limited to the pericardial cavity, where it gradually chokes the heart by increasing the intrapericardial pressure or whether it escapes into one of the pleural spaces, causing exsanguination. It is difficult to determine which of these two mechanisms occurs the more frequently although, according to Singleton⁵ massive hemorrhage is probably a more frequent cause of death than cardiac tamponade. In a series of seven cases of stab wound and three cases of gunshot wound of the heart which he reported hemorrhage into one of the pleural cavities was present in six and was the direct cause of death in three of these. Cardiac tamponade was found in two cases.

When there is a communication between the pericardial and the pleural cavities with an extensive loss of blood, transfusion is secondary in importance only to the control of the bleeding. However, it is not always easy to find a suitable donor, and unless professional donors are readily available considerable time may be lost before the necessary blood can be obtained.

Fig. 1—Laceration of pericardium enlarged to show location of heart wound.

A procedure suggested by Rhodes,⁶ which represents the easiest and quickest method of combating this blood loss, is recovery and reinfusion of the patient's own

blood. Autotransfusion, or autohemotransfusion as it is sometimes called, is not a new idea although its modern application has been limited almost entirely to the use of blood found in the peritoneal cavity following severe intra-abdominal hemorrhage notably that resulting from rupture of an ectopic pregnancy. The use of blood obtained from the pleural cavity following injury to the thoracic cage or its contents has been

regarded with suspicion because of the fear of contamination. In spite of this objection there have been no unfavorable results reported in the few cases in which it has been used, and when cultures were taken the blood was found to be sterile.

The earliest reports on the reinfusion of blood obtained from the pleural cavity were based on the experiences of army surgeons in the late war. Elmendorf, working as a battalion surgeon in the German army, reported its use in the treatment of a soldier who had a massive hemothorax resulting from a gunshot wound of the right side of the chest, which threatened to prove fatal. He aspirated 300 cc of blood from the pleural cavity and reinfused it into a vein of the arm with almost immediate improvement in the patient's condition and with ultimate recovery. Wederhake⁸ reported similar results, stating that he had used autotransfusion successfully in several cases of hemothorax due to gunshot wounds of the lung without having observed any deleterious effects.

The only other cases that we have been able to find in the literature are those reported by Brown and Debenham⁹ the hemothorax being due to fractured ribs in one case to a stab wound of the left side of the chest in another, and to a gunshot wound of the right side of the chest in a third. Autotransfusion was used in

Fig. 2—Appearance of the patient four months after discharge from the hospital.

each of these, with recovery of the patient. Culture of the blood from the hemothorax in the stab wound case was sterile.

6 Rhodes R. I. Suture of Stab Wound of the Heart. Ann Surg 81 75, 760 (April) 1925.

Rhodes, reporting his results in the treatment of stab wounds of the heart, suggested aspiration of the blood from the pleural cavity for reinfusion. "If this were done at the beginning of the operation, or even while the patient was being prepared and anesthetized, the blood collected in a vessel containing sodium citrate to prevent further clotting, it would offer the possibility of reuse, either injected into a vein or directly into the cavity of the left ventricle and might therefore be a means of saving a few additional lives." In one instance he attempted to use the blood found in the pleural cavity during operation, but it contained many clots, and before it could be filtered for reinjection the patient died.

That it is a valuable procedure worthy of trial is shown by the following report, in which we feel that it meant the difference between success and failure of the operation.

REPORT OF CASE

C. C., a white youth aged 16 admitted to the emergency room of the Presbyterian Hospital Nov. 17, 1934 had been stabbed in the left side of the chest about forty-five minutes previously. He had been working in his father's butcher shop

when he became involved in an argument with another boy over a small sum of money. His antagonist picked up a short butcher knife pressed it against his chest and asked him how he would like to be stabbed. He felt the point of the blade but had no knowledge of any injury until after he had walked about ten paces to another counter to get some meat when he suddenly felt faint and collapsed. He was brought to the hospital where he was found to be unconscious and in an extreme state of shock. He was bleeding rather profusely from a 1 cm wound in the third left

Fig. 3.—Roentgen appearance of the chest four months after discharge from the hospital.

intercostal space about 5 cm to the left of the midsternal line. The wound edges were gaping and there was a loud sucking sound on each inspiration with a soft interrupted blowing sound on expiration. The apex impulse of the heart could be felt in the fifth left intercostal space just medial to the mid-clavicular line, but was very weak and irregular. On auscultation the heart sounds were distant and muffled. The rate was estimated at between 145 and 160 beats per minute. There was no perceptible radial pulse. The respiratory rate was 50. The respirations were shallow and produced little excursion on the left side. Anteriorly the lower left portion of the chest was markedly hyperresonant to percussion while posteriorly it was flat. Breath sounds were absent over the entire left side of the chest except at the apex where they were practically normal. A diagnosis was made of stab wound of the left side of the chest, probable stab wound of the heart, left hemothorax and shock.

The patient was treated for shock and was taken to the operating room as soon as it could be made ready. Under local anesthesia an incision was made along the left margin of the sternum and then extended laterally at its ends between the second and third and the fourth and fifth ribs. The costal cartilages were divided the parietal pleura was incised and the flap was retracted laterally. There was so much blood in the pleural cavity that it was impossible to determine the

source of bleeding. With the idea of saving some of the blood for reinfusion an attempt was made to empty the pleural cavity with a large syringe, but it filled up as rapidly as the blood was removed, so this was soon abandoned in favor of large dry packs which were plunged into the cavity and were then wrung out into a beaker containing 50 cc of a 2 per cent solution of sodium citrate. Seven hundred cubic centimeters of blood was recovered in this manner. A wound was now apparent which extended through the pericardium and crossed the upper end of the anterior longitudinal sulcus of the heart having divided the anterior descending branches of the left coronary vessels without extending into the ventricle. The edges of the pericardium were grasped with Allis forceps and a tanned chromic suture on an atraumatic needle was passed through the upper angle of the pericardial wound into the heart. From above down five sutures in all were inserted, bleeding evidently being controlled by the first two. Another opening was then made in the pericardium and the surface of the heart explored for evidence of further injury. This was left open to avoid the development of a pericardial effusion. A large amount of blood fully as much as had been removed was left in the pleural cavity. The costal cartilages were approximated and the incision was closed in layers without drainage.

While the operation was progressing an intravenous set was made ready, and the recovered blood was filtered through several layers of gauze and reinfused into one of the veins of the arm. The patient had received only 200 cc of blood when he began to regain consciousness. A donor had been obtained by the time the operation had been completed but the patient's condition was considered sufficiently satisfactory not to necessitate the use of any more blood. A Kahn test of the donor's blood was subsequently reported to be positive for syphilis.

The patient was returned to his room and placed in an oxygen tent where he was kept for three days, with gradual improvement in his condition and with a steady decline of the temperature, pulse and respirations toward normal. The blood pressure remained constant at 130 systolic and 80 diastolic. Examination of the blood showed 3,200,000 red blood cells and 73 per cent hemoglobin (Sahli). After removal of the oxygen tent his condition remained unchanged except for a daily elevation of temperature and evidence on physical examination of an increasing amount of fluid in the left pleural cavity. Aspiration of the chest on the seventh day yielded 900 cc of a sterile serosanguineous fluid and similar amounts were removed every other day until the eleventh day when the upper angle of the wound broke down resulting in an open hydropneumothorax. This was followed by the development of an empyema showing *Staphylococcus aureus* which was controlled fairly well by postural drainage until the twenty-second day when the incision was finally healed. Aspirations of the chest were again resorted to with the removal of about 500 cc of pus every third or fourth day. A transfusion of 300 cc of citrated blood was given as supportive treatment. Repeated roentgen examinations of the chest eventually revealed a walling off of the empyema cavity limiting it to the upper half of the left side of the chest and this was drained by means of a rib resection on the sixtieth day. Following this his convalescence was entirely uneventful and he was discharged from the hospital eighty-three days after admission. Examination at this time was negative, except for some diminution in the anteroposterior diameter of the left side of the chest with evidence of thickened pleura. An electrocardiogram was reported as showing signs characteristic of early coronary involvement.

Four months later he returned for examination stating that he felt fine and was working again. The chest was essentially unchanged except for some improvement in the deformity and a roentgenogram showed thickened pleura but normal heart and lung shadows. An electrocardiogram was negative.

SUMMARY

Autotransfusion was used to combat the excessive loss of blood resulting from a stab wound of the heart.

As far as we can determine by a review of the literature this is the first time autotransfusion has been used in the treatment of this type of injury. In view

of its marked success in this instance, we believe that it should receive further trial as an adjunct to cardiorrhaphy in those cases in which the loss of blood is sufficient to threaten the immediate survival of the patient

PAIN IN THE SHOULDER GIRDLE, ARM AND PRECORDIUM DUE TO CERVICAL ARTHRITIS

SAMUEL S. HANFLIG, M.D.

BOSTON

This paper is concerned with the study and treatment of a group of cases in which, with the exception of one, the outstanding symptom was pain in the vicinity of the shoulder girdle and arm. In these cases, evidence of local disease of the arm and shoulder was absent and the pain was probably a manifestation of irritation or actual inflammation (radiculitis) of cervical spinal nerve roots due to cervical arthritis. In the one excepted case, precordial pain was the outstanding feature and was similarly due to a radiculitis or irritation of nerve roots due to cervical arthritis. It is believed that cases of this type are more frequent than is generally supposed. Their prompt recognition has led in most instances to complete therapeutic relief. The present paper is essentially a clinical one with emphasis on diagnosis and treatment, some reference being made to the pathologic process and its correlation with the clinical features. The method of treatment outlined, that of stretching and manipulation with a proper apparatus, has been of value in doubtful cases as a diagnostic test.

PATHOLOGY

The intervertebral foramina, through which spinal nerve roots emerge, are completely surrounded by bony structures. Surrounding the nerve root within the foramen are cellular tissues, lymphatics, arteries and veins. Consequently a congestive process, a periostitis and inflammation or an osteophyte within this bony passage may cause root symptoms.

Because of the dearth of autopsy material in cases such as these presented here, Nathan¹ induced nonsuppurative arthritis in animals and searched for evidences of spinal involvement. In six cases he found spinal arthritis, and the pathologic changes he observed were as follows:

- 1 Epidural exudate infiltrating the epidural areolar spaces

- 2 Involvement of costovertebral joints with thickening of connective tissue in the neighborhood

- 3 Thickening of the periosteum of the vertebrae

He concluded that the vertebral changes in acute spondylitis (assuming that the pathologic changes are analogous to those found experimentally in the dog) consist of endothelial and subperiosteal inflammation leading to epidural and perispinal exudation, with resulting root irritation and compression.

CLINICAL AND PATHOLOGIC CORRELATION

The clinical features of arthritis of the cervical spine are these. Rigidity is present and its extent varies

with the degree of muscular spasm, the extent of ligamentous ossification and the presence of osteophytes or hypertrophic changes. In the acute or infectious variety the rigidity is due to muscular spasm. In more advanced cases, ligamentous ossification is the cause. In far advanced cases, the osteo-arthritic or hypertrophic variety, the rigidity is due to osteophytes growing at the margins of the vertebral bodies and on spinous and transverse processes.

Another clinical feature is pain. It may be local pain due to the strain to which the inflamed parts are subjected while the spine is called on to maintain correct erect posture without support. On the other hand, the pain may be referred along the sensory nerves of the limbs or trunk. This pain may be due to pressure on the posterior nerve roots as they emerge from the spinal cord through their bony outlet. This pressure may be due to one or more causes. In the infectious variety the roots as they emerge may be involved by adhesions or pressed on by inflamed ligaments and capsules. In the hypertrophic variety, reference of pain may be due to the pressure of osteophytes with their associated soft tissue inflammation and synovial thickening.

Symptoms may vary, depending on the degree of mechanical interference with the roots as they emerge from the cord. If the interference is slight there may be paresthesias and numbness as the only symptoms. Pain of a more severe sort along any of the sensory or segmental nerves is the inevitable sequence of a more definite impingement. The distribution of pain and sensory disturbances varies with the particular nerve root or roots involved. The mechanism of reference of pain to the precordial areas as a result of irritation of cervical roots has been suggested by Nachlas.² The medial anterior thoracic nerves originate in the eighth cervical and first thoracic spinal segments. The lateral anterior thoracic nerve originates in the sixth and seventh cervical segments. These innervate the pectoralis major and pectoralis minor muscles. These are motor nerves and do not carry any skin sensory fibers. These nerves, however, can possess protopathic sensations so that an irritation of them may produce a diffuse yet definite pain referred to the terminal portion of the nerve. There may even be muscle incoordination, loss of position sense, or even absence of reflexes and paralyses of the flaccid variety if the anterior roots of the spinal nerves are sufficiently involved.

FREQUENCY

The syndrome of cervical arthritis, more often the hypertrophic variety, associated with referred pain to the shoulder and arm, and more rarely to the precordium in a pseudo-angina fashion, is common. In the past three years approximately thirty cases have come to my attention. In these the diagnosis was made and confirmed and treatment was successfully instituted.

CASE HISTORIES

Of this series, five cases are presented in all of which pain in the shoulder and arm due to cervical arthritis was present. A sixth case will be mentioned briefly as a case of anginal-like pain, believed to be due to cervical arthritis. In none of these cases was there any evidence clinically and by roentgen examination of pathologic changes in the shoulder joint. In all these cases, either clinically or by roentgen examination a diagnosis of arthritis of the cervical spine was made. All were

relieved by the treatment suggested by the cases herein presented, with the aid of the apparatus shown in figures 2 and 3

CASE 1—E S, a man, aged 43, a merchant, complained of a constant "agonizing pain" along the posterior aspect of the right shoulder, which had been present for about six weeks. This pain radiated up along the right lateral aspect of the neck and down into the fourth and fifth fingers. It had been suffi-

Fig 1—Hypertrophic arthritis of cervical spine

ciently severe to interfere with his sleep. He had noticed for even a longer time numbness of the right hand and weakness of the right grip. A diagnosis of subdeltoid bursitis was made by his family physician and baking and massage and salicylates were prescribed without relief.

Examination of the right shoulder joint was negative. The cervical spine showed limitation of motion to a slight degree in all directions particularly in rotation. When an attempt was made to stretch the neck in rotation to the right beyond the limit he was actively capable of the pain in his shoulder was acutely accentuated. Examination also revealed marked atrophy of the extensor muscles of the right upper arm and weakness of the right wrist extensors. The reflexes of the right arm were diminished. The right hand grip as compared to the left was definitely impaired. Roentgen examination revealed marked spurring involving the anterior and lateral borders of the fourth, fifth, sixth and seventh cervical vertebrae with practically complete bridging of the spaces between the fifth and sixth vertebrae. A roentgenogram of the right shoulder was negative (fig 1).

He was admitted to the Beth Israel Hospital and the morning after admission treatment was begun as follows. One-half hour before the patient was taken to the stretching and suspension apparatus 3 grains (0.2 Gm.) of sodium amytal was given. He was seated in a chair under the Savre head traction apparatus and traction was applied in a manner suggested in figures 2 and 3. Traction was continued until the buttocks swung freely just above the seat of the chair. While suspended in this position the patient indicated the desire to be lowered by snapping his fingers, since the apparatus made it impossible for him to speak. When the apparatus was released he stated that while he was suspended, the pain which had been present constantly for six weeks disappeared completely. He also volunteered the information that as he was lowered and as traction was discontinued the pain returned. Treatment was carried out again for several short periods of one or two minutes and during these suspensions with a nurse steadying the shoulders the head was passively rotated to the left and to the right just beyond the limits of active rotation. A

Thomas collar was made and applied, and he was returned to his room, where hot fomentations were applied to the neck.

This procedure was carried out three times on the first day. It was not necessary to repeat the use of amytal. It was performed twice on the second day, and on the third day he was discharged from the hospital with instructions to remove his collar for short periods of hot fomentations to be followed by active neck exercises in flexion, extension and rotation. He was stretched occasionally at home and at the end of eleven days the only pain persisting was a very slight one over the back of the right shoulder. At this visit there was slight numbness of the little finger. A month later all the pain had disappeared and the right grip as well as the extensors of the right elbow and wrists had improved. Three months after treatment was begun he was completely well and has continued so to date, two years later.

CASE 2—W H, a business man aged 45, complained of severe pain of three weeks' duration along the right side of the neck. The onset was gradual and there was no injury associated with it. The pain radiated to the superior aspect of the right shoulder and into the lateral aspect of the right upper arm. Questioning revealed similar attacks of moderate intensity extending back over a period of several years. The most recent attack had been unrelieved by bakings to the shoulder administered by a physician who made the diagnosis of bursitis of the shoulder.

Examination of the right shoulder showed no evidence of any active disease. The neck, however, showed limitation of motion to a slight degree in all directions. Pain in the shoulder was accentuated by forcing forward flexion beyond the range he was actively capable of. Poentgen examination of the cervical spine showed slight hypertrophic changes.

Fig 2—Suspension of patient with overhead block and tackle and Savre head-ling

The same treatment as in case 1 was carried out at the Beth Israel Hospital. Here again in the suspended position the pain disappeared, only to reappear when the patient was lowered. After two weeks of treatment he was completely well.

CASE 3—J S, a man, aged 55, a druggist, the brother of patient 1, complained of acute pain along the lateral aspect of the right side of the neck radiating into the right upper arm. It had been present more than a week and was constant and unendurable.

Examination of the shoulder joint was negative, as was also a roentgen examination. Motions of the neck were markedly limited in all directions. Forced extension beyond his active extension accentuated his pain. Roentgen examination of the cervical spine showed extensive hypertrophic changes so identical with the changes revealed in his brother's roentgenogram, even to the bridging of the spurs, that the two could be interchanged and confused readily.

He was admitted to the Beth Israel Hospital and treatment was instituted. Within three weeks the pain was entirely gone. Six months later he had a mild recurrence of this pain, which responded effectively and promptly to exercises and hot applications.

CASE 4—M D, a man aged 60, complained of pain along the dorsum of the cervical spine and over the back of the left shoulder. This pain had been constant for nine weeks during which time several physicians had treated him without success. His teeth were extracted without relief. Following this he was advised to have his tonsils removed but the consultant to whom he was referred for this procedure did not consider it necessary and suggested an orthopedic consultation.

Examination of the left shoulder was negative. The neck showed limitation of motion in all directions with pain referred on forced rotation to the left to the posterior aspect of the left shoulder. Roentgen examination of the cervical spine showed extensive liping and hypertrophic changes with a good deal of bridging of spurs.

He was admitted to the Beth Israel Hospital for treatment. In ten days he was free from pain. He was advised to continue with exercises at home. He was stretched once a month for three months. He has been well to date, one year after treatment ceased.

CASE 5—L L, a furniture dealer aged 55, complained of pain in the right shoulder of one week's duration. It was root-like and lancinating unrelated to any initial trauma or to motions of the shoulder joint. Two months before the onset of pain he had consulted a cardiologist for precordial distress present on repeated occasions with exertion. For this condition he was advised to diminish his activities. Small doses of glyceryl trinitrate were prescribed for this distress.

Examination of the right shoulder joint was negative but for a rather severe second degree burn over the superior and anterior aspect of the shoulder joint, the result of a too vigorous attempt to allay the pain with hot fomentions. Roentgen examination of the neck revealed no evidence of hypertrophic arthritis of the cervical spine. Objectively however the neck showed slight limitation of motion in all directions, and forcing his neck in lateral flexion to the left accentuated the pain.

He was admitted to the Beth Israel Hospital and before treatment was instituted he was thoroughly examined by an internist who shared my opinion that the present pain was in no way related to angina pectoris and questioned the existence of coronary disease. Treatment was carried out and in four days the patient was discharged with marked improvement. Three weeks afterward the pain had subsided and only numbness over the superior aspect of the right shoulder remained. This lasted for about a month. He has had no precordial distress since the treatment. Whether or not this is due to his care not to overexert or whether the anginal pains were possibly due to the cervical arthritis is recently described by Nachlas cannot as yet be definitely established.

Case 6 is being presented briefly, as it is to be reported more fully elsewhere by others primarily interested in cardiology.

CASE 6—H T, a man aged 50 presented himself at the outpatient department of the Beth Israel Hospital in December 1933 complaining of pain beginning to the left of the sternum radiating into the lateral left side of the neck and down his left arm. It was associated with a constant pain and tightness of the back of the neck. He had been seen previously and elsewhere by a cardiologist who made a diagnosis of angina pectoris, prescribed glyceryl trinitrate and shortly thereafter suggested a total thyroidectomy for the relief of the pain. The patient refused to undergo this operation. He was studied at the various clinics of the Beth Israel outpatient department.

The reported heart examinations both clinical and laboratory were negative. The positive observations were as follows: hypertrophic arthritis of the cervical spine and left shoulder, generalized arteriosclerosis and a moderately increased total protein in the spinal fluid on two occasions. This increased total protein was the only positive neurologic manifestation. A diagnosis of radiculitis with associated precordial pain as suggested by Nachlas, was considered by the neurologic service. The possibility of a cord tumor was also considered.

I suggested that treatment as outlined in this paper might be used as a therapeutic test. Two days after it was begun the precordial pain disappeared, along with a good deal of the neck pain. A few days later the precordial pain recurred but was considerably diminished. It was immediately controlled by additional treatment and two or three days thereafter the pain had entirely gone. The patient has discontinued all medication and is most anxious to receive additional stretchings. His only complaint at present is pain in the left arm and shoulder which is believed to be due to a grossly objective arthritic left shoulder. He has been followed now for seven weeks to date (Oct 15, 1934) without any recurrence of the precordial pain.

DIAGNOSIS

The diagnosis is suggested by the presence of pain, root-like in character, in the shoulder, arm or precordium unassociated with sufficient evidence of local disease in the shoulder to account for it satisfactorily. Sensory disturbances and even definite flaccid paralysis with loss of reflexes may be present. There is usually some pain either along the side of the neck or back of the neck, which either may be the starting point for the pain in the arm, shoulder or chest or may exist independently. Examination of the neck usually reveals limitation of motion, to a less or greater degree, in one of its arcs. Passively stretching the neck in all directions beyond the range of which the patient is actually capable will usually disclose the direction in which the pain is accentuated.

Fig 5.—Rotation of patient's head while suspended with shoulders held fixed.

The roentgenogram may or may not show evidences of hypertrophic arthritis, depending on the extent, duration and type of disease. The condition must be differentiated from (1) cervical rib, (2) subacromial bursitis, (3) arthritis of the shoulder, (4) toxic and infectious neuritis, (5) muscle sprain, and (6) lesions of the spinal cord.

TREATMENT

The treatment of this disorder, although essentially constant, may vary in its sequence and duration with the activity and acuteness of the arthritic changes. If the arthritis responsible for the pain is of the acute variety it is desirable to splint the neck either with a Thomas collar or with constant head traction using a Sayres sling.

If the arthritis is subacute or chronic, and this is the usual type, stretching and manipulations are indicated in the manner hereafter described. An overhead hook into which can be attached a block and tackle Sayres

sling suspension apparatus is needed. The patient is seated on a chair under the apparatus. If the patient is apprehensive, it may have been advisable to prescribe a sedative. The Sayres sling, well padded at the chin piece and occiput piece, is applied. Traction is applied as in figure 2 and is continued until the patient's buttocks swing freely, when rocked, just above the seat of the chair. While the patient is suspended in the air, the shoulders are held by an assistant, and the head and Sayres sling are rotated (fig. 3) to the left and right, forcibly. This procedure is repeated several times. The patient is then lowered and rested for a moment or two, and then the entire procedure is carried out again.

A Thomas collar is made and applied, to be removed only for the hot fomentations to the neck that follow each treatment.

It has been customary to carry out this treatment three times the first two days, twice a day thereafter and then spaced out as seems advisable. The number of treatments varies tremendously and is determined by the progress of the disorder. Similarly the period of wearing the Thomas collar varies. In certain cases it may be dispensed with.

As soon as the pain begins to go, active graded exercises in rotation, flexion and extension are advised. The patient is advised to return at stated long intervals for inspection, at which time occasional neck stretchings and manipulations are advised if any recurrence of pain or increase in limitation of motion is observed.

This treatment can be used as a diagnostic test because in most cases in two or three days there is beginning relief of pain. It is effective as a treatment probably because it mobilizes adhesions, breaks up bridging of fine calcifications, and relieves muscle spasm, thereby contributing to a better carriage of the cervical spine.

COMMENT

The occurrence of an increased total protein in the spinal fluid in case 6 suggests the possibility of such a finding in radiculitis of this type, consistent with the observation that the cerebral spinal fluid circulates around the nerve roots as they lie in the intervertebral foramina. It is not unreasonable to assume that the cerebral spinal fluid may be modified by the radiculitis as the result of pressure and the associated congestive and inflammatory changes of spondylitis of the spine. Lumbar puncture will be done in additional cases when possible, with a view to establishing or disproving this premise.

I have used this treatment as a therapeutic test in several instances to differentiate between this condition and others in which the objective signs were confusing. Its possibility as a therapeutic test in the differentiation of pseudo-angina due to cervical arthritis and true angina has been suggested.

These cases are frequent and they represent in all probability a substantial proportion of the patients who migrate to chiropractors and others after they have been bled at length for arthritis of the shoulder or bursitis of the shoulder. Some of the commonly called neuritis in elderly people is probably on this basis.

The recognition of these borderline cases which lie between the confines of neurology and orthopedic surgery is most important if one is to prevent a substantial migration of patients to the cults beyond the realm of medicine.

PERSISTENT URACHUS IN THE ADULT

CLIFFORD LEE WILMOTH, MD

STATEN ISLAND, N. Y.

Umbilical fistulas derived from remnants of the urachus are rare, particularly in adults. Four cases of pathologic conditions originating in the urachus, seen at the U. S. Marine Hospital, Staten Island, during the past five years are reported. One was a malignant growth, the other three cases were chronic fistulas.

At birth the urachus reaches to the umbilicus. Normally, after birth the bladder descends, taking the urachus with it, leaving only a fibrous tissue cord. In the normal adult the urachus measures from 3 to 10 cm. in length and reaches only one third the distance from the apex of the bladder to the umbilicus, being attached at the umbilicus only by fibrous cords from the obliterated umbilical arteries.

In a small percentage of cases, however, such descent of the urachus does not occur, and there remains a more or less obliterated epithelial structure reaching from the umbilicus to the bladder. That this is a rare condition is evidenced by the report that of 15,000 cases admitted to the Brady Urological Institute only three were found to present this condition. Of 5,840 cases seen at this hospital during the past five years, three have presented this condition and were diagnosed not by cystoscopic examination but by examination of an umbilical fistula and the diagnosis was confirmed by

Fig. 1.—Drawings of the four cases. U, umbilicus; B, bladder; F, fistula or cyst of urachus; D, obliterated lumen of urachus.

operation. The fourth case was diagnosed by an exploratory operation for a tumor extending from the umbilicus to the pubis, which was found to be a malignant growth with metastases extending down over the bladder and invading the adherent omentum.

The normal urachus is attached to the apex of the bladder. It may communicate with the bladder or it may reach only to the bladder mucosa. The urachus is separated from the peritoneal cavity only by the parietal peritoneum. The lumen of the normal urachal canal is approximately 1 mm. in diameter and is lined by epithelial cells. While the canal presents an unbroken continuity of epithelial cells, the lumen may be obstructed by its own desquamated epithelium. The obstruction offered by the proliferated and shed epithelial cells and debris accounts for the rarity with which urine is found to pass upward from the bladder. Surrounding the epithelial lining of the normal urachus is a dense, connective tissue layer. The epithelial cells tend to proliferate outward into this connective tissue support.

On those rare occasions in which the urachus does not descend with the bladder a lumen may be intact, reaching from the bladder to the umbilicus and discharging urine at the umbilicus. In other cases the

lumen may be patent only to the midportion with no drainage present, unless as the result of injury or secondary infection, the contents of the infected cyst find their way upward to be discharged at the umbilicus, or downward into the bladder, with a resulting secondary cystitis. In other cases the lumen appears to open at the umbilicus and to extend downward, for a distance of from 5 to 10 cm, apparently ending blindly.

In none of the cases reported here was there a lumen connecting with the bladder. In case 1 the inflammatory swelling extended to the mucosa of the bladder but not into it. In case 2 the lumen was present, extending from the umbilicus downward 5 cm, ending blindly, while 2 cm below there was a cyst filled with a straw-colored transparent fluid, 3 cm in diameter. From this cyst a cord extended downward to the apex of the bladder. In case 3 the fistula extended from the umbilicus downward approximately 5 cm, ending blindly. In case 4, in which the malignant growth was present, the tumor mass extended from the umbilicus and involved the bladder. It was difficult to determine the extent of the urachus as the tumor had extended downward along the wall of the bladder, although it had not penetrated the mucosa.

Infection in a persistent undescended urachus makes its presence more evident. The history in these three benign cases is similar. The chief complaint was an intermittent discharge from the umbilicus. There was a slight more or less constant secretion present, which periodically became purulent and was associated at such times by slight pain and redness about the umbilicus. When the infection subsided the discharge again became a thin, watery secretion which kept the umbilicus damp, but only occasionally was it sufficient in amount to soil the clothes. One patient complained

secondary infection, the patient is conscious of a tender swollen area or a draining sinus. This periodically drains a purulent material as secondary infection flares up. Such is also the history and course of symptom-producing urachal remnants.

The treatment is excision of the infected tract and remnants of the urachus. If there is an opening at the

Fig 3 (case 2)—Persistent urachus. The structure is lined by stratified transitional epithelium similar to that of the urinary bladder. It is surrounded by fibrous tissue.

Fig 2 (case 2)—Tract leading to umbilicus from persistent urachus.

of a foul odor which was quite noticeable. The odor was similar to that experienced in cutting into certain sebaceous cysts. The symptoms and course were almost identical with those of the common pilonidal cysts. In pilonidal cyst the epithelium has remained buried and symptomless as a rule until adult age. For some reason, owing to increase in the secretion or as a result of

umbilicus, the sinus may be injected with methylene blue, which may aid in removing the entire epithelial structure. The sinus, if present, is then closed by suture and gauze packing to prevent soiling of the abdominal wound. An incision is then made about the umbilicus, extending downward near the midline toward the pubis.

The peritoneum may be found adherent owing to the infection, and in two of the cases the omentum had plastered over the region from the umbilicus downward along the infected tract. The presence of the adherent omentum makes the possibility of a Meckel's diverticulum more difficult to rule out, so one must proceed with caution. Theoretically, a simple extraperitoneal excision of the sinus tract is possible. Practically, such a tract is densely adherent to the peritoneum, and the peritoneum must be removed with it for the extension of the cyst. Even with care it is difficult to remain outside the infected area, as it is necessary to preserve as much peritoneum as possible if satisfactory closure is to be made. By opening the peritoneal cavity contamination may occur, and difficulty is often experienced in closing the peritoneum without undue tension. In one case closure was made with difficulty, and then only by sutures that included the entire abdominal wall, except the skin. As in pilonidal cysts, incision into the infected cyst does not produce a cure but may be a necessary preliminary operation to establish drainage until the acute infection subsides to a minimum. After the acute infection has ceased, a safer excision of the entire tract may be accomplished. In these cases there was no evidence of urinary obstruction, nor a history of urinary infection. Nevertheless the entire urachus was removed and the protruding apex of the bladder closed with interrupted sutures.

REPORT OF CASES

CASE 1—A youth, aged 19, admitted to the hospital, Sept 24, 1933, complained of pain about the umbilicus and a discharge from the umbilicus. The condition was first noticed six weeks before. The first symptom noted was a small amount of pain about the umbilicus which three days later began to drain. At times the patient noticed considerable local pain extending

Fig 4 (case 2)—Wall of cyst along the course of the urachus. The cyst is lined with simple low cuboidal epithelium and has a wall of hyaline lamellar connective tissue.

from the umbilicus downward and that there was swelling in that area. He had had no urinary symptoms. The urine was apparently normal on admission.

The temperature and pulse were normal and physical examination showed little of importance except the draining sinus from the umbilicus and a tender area along the midline extending downward toward the pubis. The sinus was injected with methylene blue. An incision was made about the umbilicus and extending downward at the midline toward the pubis.

A persistent urachus measuring 2 cm by 4 cm by 8 cm was found. It was slightly pear shaped with the smaller end toward the bladder. The tumor was attached to the fundus of the bladder but did not penetrate the mucosa. The peritoneum was firmly adherent to the tumor mass and was removed with it. The omentum was adherent along the course of the urachus. The urachus was removed and the opening in the fundus of the bladder closed. The abdominal wall was closed with difficulty owing to loss of peritoneum.

Sections¹ showed a small tubular structure 6 mm in diameter lined by columnar epithelium. A thin circular layer of smooth muscle was present about the epithelium. Outside this layer was loosely bound muscle and fibrous tissue. There were multiple sinus tracts lined by granulation tissue extending outward from the epithelial-lined urachus.

There was moderate drainage with elevation of temperature for nine days following operation. Recovery after that time was uneventful.

CASE 2—A man aged 27, was admitted to the hospital Dec 2, 1934 for excision of a persistent urachus. At the time of admission he stated that he had noticed a discharge from the umbilicus for the past month. The drainage at times had a noticeably foul odor. The discharge was thin and slightly yellowish. The amount, he thought was gradually increasing.

Examination showed slight redness about the umbilicus. There was a small amount of foul smelling watery secretion from a sinus, which extended downward a distance of 1½ inches in the midline of the abdominal wall. The odor of the discharge resembled that noted in an occasional dermoid cyst.

The temperature and pulse on admission were normal. There were no urinary symptoms. The urine was normal.

The sinus was injected with methylene blue. An incision was made encircling the umbilicus and extending downward toward the pubis near the midline. The persistent urachus was removed. It was necessary to remove a small area of peritoneum adjoining the umbilicus. For the remainder of the excision the peritoneum was not incised.

Examination showed a tract lined with atrophied transitional epithelium similar to that of the urinary bladder. This epithelial tract was surrounded by fibrous tissue. The cyst was lined by cubicle epithelium with an outer wall of hyaline connective tissue. The microscopic diagnosis was urachal cyst with persistent urachus. Postoperatively there was an elevation of temperature for seven days, with moderate drainage from the wound. Recovery was otherwise uneventful.

CASE 3—A man aged 38, examined Jan 24, 1935, stated that about two years previously he had first noticed a slight watery discharge from the umbilicus. The discharge had persisted most of the time during the past two years. At intervals there was redness about the umbilicus and the discharge became thicker. Usually the amount of secretion was just sufficient to keep the umbilicus damp and seldom soiled his clothes except at those intervals when the discharge became more purulent and it was necessary to wear a dressing over the umbilicus to prevent soiling.

Examination showed a rather deeply placed umbilicus and at the inferior margin there was a small sinus. A probe was passed without difficulty directly downward in the midline for a distance of 4 cm. There was a thin, watery discharge from the sinus.

Operation was advised, but the patient stated that he had recently obtained a new position and felt that he could not ask for leave to be operated on at that time.

CASE 4—A man, aged 31, admitted to the hospital Aug 28, 1930, complained chiefly of pain and difficulty in urination which had been noticed for a period of one month.

Fig 5 (case 4)—Myxosarcoma arising in a persistent urachus. Sections show a new growth composed of large cells with vesicular nuclei and small nucleoli. Where close packed these cells show broad faintly staining cytoplasm and polygonal outline and numerous fine mucin and collagen fibrils run around and between the cells. Where the arrangement is loose the cells assume a stellate form and copious intracellular mucin. Mitotic figures are numerous.

Examination was essentially negative except for the abdomen. There was a palpable tumor mass extending from the umbilicus downward to the pubis. Cystoscopic examination showed compression of the fundus of the bladder apparently from an extravesical mass. The bladder mucosa appeared normal. The leukocyte count was 8600. The urine was normal.

¹ Microscopic sections furnished by the National Institute of Health, Washington, D. C. Photomicrographs made at the Veneral Disease Research Laboratory, U. S. Marine Hospital, Stapleton, S. I.

An exploratory incision was made. A tumor mass was found invading the abdominal wall and extending into the rectus abdominis muscles laterally from the umbilicus downward toward the pubis and then extending over the superior surface of the bladder into the pelvis. The adherent omentum was filled with tumor masses. There were metastatic growths scattered over the adjacent parietal peritoneum.

The tumor was inoperable. Microscopic sections showed the tumor to be a myxosarcoma. Roentgen therapy gave no apparent results.

The patient died from generalized sarcomatosis five months later.

SUMMARY

Of four cases of persistent undescended urachus in adults one was malignant. The three nonmalignant ones opened at the umbilicus.

While the normal urachus should descend with the bladder after birth, some do not descend and the secretion from the epithelial lining or secondary infection of the epithelial structure causes sufficient pressure to produce an opening at the umbilicus with resulting chronic fistula.

The age of the patient when first noted, the onset of symptoms, the progress of the condition and the treatment are nearly identical with the common pilonidal cyst, differing only in its embryologic structure and its different location.

Surgical removal of the sinus and epithelial structure in its entirety with the umbilicus and inversion of the bladder end is a proper method of treatment. Malignancy does occur in the persistent urachus.

FATAL HEMOGLOBINURIA WITH UREMIA FROM QUININE IN EARLY PREGNANCY

K. L. TERPLAN, MD

AND

C. T. JAVERT, MD

BUFFALO

As it is not generally known to the physician that quinine when employed in early pregnancy, may produce hemoglobinemia with severe kidney damage, we report a case of fatal quinine poisoning in a woman in the early stage of pregnancy with hemoglobinuria and anemia. The case also stresses the importance of a thorough pathologic and toxicologic examination in any instance in which the clinical observations are not fully explained by the laboratory data. The urea nitrogen retention in the blood of this patient was the highest ever recorded in our laboratories. This together with increasing oliguria, focused the clinical attention on the kidneys. Since mercury poisoning was ruled out by the analysis of the urine and a history of drug ingestion could not be obtained before the death of the patient, it remained for the postmortem examination to determine the nature and etiology of the anticipated severe renal damage. Here the picture of so-called hemoglobinuric infarction of the kidney tubules suggested itself. Search of the foreign literature showed in rare instances that quinine was found as the only ascertainable cause of fatal hemoglobinuria. This case is to our knowledge the first in which part of the drug taken could be recovered by chemical analysis of the liver. It is apparently the first report in the American literature of fatal hemoglobinuric kidney damage due to quinine.

History.—A woman aged 41 of Polish descent admitted Sept. 12, 1934 in the service of Drs. Greenc and Bowen had had three previous normal pregnancies. Her chief complaints were persistent emesis, anorexia, extreme prostration and vaginal bleeding supposedly of several weeks' duration. Further history was refused because of extenuating circumstances and the following information was obtained from the immediate family after the death of the patient. A pregnancy of approximately three months duration had been interrupted by a lay abortionist who had given the patient the following drugs: Liquor Sedans (a proprietary remedy containing black haw, golden seal and Jamaica dogwood) twenty 5 gram (0.3 Gm.) tablets of quinine, six bile salt tablets and twenty-four black pills. The manner of ingestion and the dosage of the medications were not discovered as the patient would give no information concerning these facts. For the same reason the exact date of the onset of symptoms could not be determined. Medical attention was not sought until the patient's condition became rather critical and the family quite alarmed which was one day prior to hospitalization. However several of the aforementioned black pills were obtained and analyzed.

Examination.—The patient was pale and obese with a temperature of 98 F. (rectal), pulse 82, and respiration rate 20. The conjunctivae were anemic, there were brown crusts on the tongue and colostrum was expressed from both breasts. There were no cardiac bruits demonstrable, the blood pressure was 110 systolic, 66 diastolic and the abdomen was soft. Pelvic examination revealed the presence of slight vaginal bleeding, an open cervical canal and a slightly enlarged uterus. Pitting edema of the ankles was present and also a maculopapular eruption on the back and the buttocks.

The urine was first reported to be clear, with a specific gravity of 1.015, a 2 plus albumin, and no sugar. The red cell count was 1,830,000 per cubic millimeter with a hemoglobin of 36 per cent (Newcomer). The white cell count was 19,800 with 96 per cent of polymorphonuclear neutrophils. The Wassermann reaction was negative.

Chemical analysis of the blood revealed urea nitrogen 344, dextrose 262, chlorides 479, calcium 6.6, phosphorus 20.4, cholesterol 221, creatinine 16.2 and uric acid 20.9, all expressed in milligrams per hundred cubic centimeters. The blood serum contained 34 per cent of albumin and 17 per cent of globulin. The plasma carbon dioxide capacity was 15 volumes per cent. The van den Bergh reaction was 0.6 unit. Several urine samples were negative for mercury bichloride.

Treatment and Course.—Despite a daily injection of from 3,000 to 4,000 cc of saline solution containing 5 per cent dextrose, distinct oliguria was present, only from 300 to 400 cc of urine was excreted in twenty-four hours. A blood transfusion of 450 cc was given. During the final days of life the urine became loaded with red blood cells. The patient became increasingly lethargic, comatose and dyspneic, vomited at intervals and had a pulse of very poor quality. The temperature even immediately prior to death remained constantly subnormal (97 F., rectal), the pulse rate at its highest was 110, and the respiration rate 28. She died six days after admission.

Necropsy.—This was performed five hours after death. The pathologic diagnosis with only the salient changes mentioned was Hemoglobinuric infarcts of both kidneys, diffuse glomerulonephritis (?). Distinct uremic gastritis and enterocolitis with strong ammoniacal odor. Edema of the liver with slight brownish discoloration (hemosiderosis). Contracted bladder containing very little bloody urine. Very distinct anemia of the entire integument with a marked peculiar grayish hue. Purpuric rash on the back and sacral region. Fluid dark red blood in the heart and in all large veins. Distinct edema of all the mediastinal tissues, marked edema of the gallbladder. Petechial hemorrhages in the pericardium, the gastro-intestinal mucosa and brain. Necrotic placental remnants in the uterus without signs of an endometritis. Recent lobular pneumonia. Normal lipid content in the adrenals.

Macroscopic Examination of Kidneys.—The kidneys were markedly enlarged, each measuring 14.6 by 7 by 4 cm. One weighed 260 Gm. and the other 255 Gm. The capsule was markedly distended but stripped easily. The surface of the cortex showed a peculiar discoloration. It was grayish brown with a black hue somewhat resembling the color of chocolate. There were innumerable dark bluish black spots scattered over

the cortex. These were interspersed with grayish white areas resulting in a mottled appearance. On section the parenchyma was very moist. The cortical substance appeared distinctly swollen, varying in width from 0.8 to 1.4 cm. There were innumerable bluish brown streaks especially prominent in the renal pyramids. The entire picture resembled that of so termed hemoglobinuric infarcts (fig 1).

Microscopic Examination of Kidneys—The most conspicuous changes were hemoglobin masses forming fine granular detritus

Fig 1—Gross appearance of the kidney on surface and cross section

in the lumen of many convoluted tubules, in the loops of Henle and in the distal convolutions. In addition, most of the collecting tubules contained huge conglomerate hemoglobin globules and many desquamated epithelial cells with preserved nuclei, which were completely imbibed with hemoglobin. There was marked distention of practically all the convoluted tubules and the loops of Henle. Some of Bowman's capsules also showed dilatation, although but little dissolved hemoglobin was detectable, together with desquamated epithelial cells and some leukocytes. However the hemoglobin casts and masses that were so conspicuous in the convoluted and collecting tubules were not seen in Bowman's capsules. The epithelial damage in the proximal convoluted tubules was most severe. They exhibited necrobiotic changes and complete necrosis. In certain areas the epithelial lining appeared collapsed almost to a very thin membrane. Many nuclei were missing and the cell membranes were not preserved. The brush border was hardly visible. The collecting tubules, however, were much less distended. It was obviously difficult therefore, to identify the different portions of the tubular system because of the severe degenerative lesions and the extreme distention of the lumens.

In addition to the unusually marked hemoglobinuria with the degenerative lesions in the epithelial cells there were also rather marked inflammatory lesions as evidenced by leukocytic and plasma-cellular infiltrates not only around the collecting tubules overloaded with hemoglobin but also around several glomeruli and proximal convoluted tubules. This infiltration had, especially in the cortex, a more focal distribution. Finally, there were many leukocytes and necrotic cells intermingled with hemoglobin in the lumen of a fair number of loops of Henle and some of the collecting tubules. Only a few glomeruli appeared rich in cells and their capillaries contained many leukocytes. Iron stain (Turnbull method) showed distinct hemosiderin granules in the epithelial cells of some convoluted tubules and loops of Henle, but only a few of these pigmented cells were visible within the hemoglobin casts in the collecting tubules. Otherwise the iron reaction in the fine granular and globular hemoglobin masses and casts was entirely negative. It was of special interest to note that the erythrocytes within the capillaries of the glomeruli as well as in the stroma between the tubules and in the medulla were for the most part well outlined. Only occasionally were shadows of the erythrocytes seen, and some of them showed only a faint color, which suggested that the hemoglobin content was markedly reduced.

Other Microscopic Changes—Smears of the urine sediment from the bladder showed huge hemoglobin masses and prac-

tically no preserved erythrocytes, together with a large number of leukocytes and epithelial cells. Spectroscopic examination suggested but did not conclusively prove the presence of methemoglobin.

Especially striking was the histologic picture of the liver which showed a most selective hemosiderosis of the Kupffer cells. There was no iron pigment demonstrable in the liver cells.

The reticulum cells of the splenic pulp also showed distinct hemosiderosis.

Chemical Analysis—Dr Edward J. Powers, chemist in the Department of Health, Buffalo, made the analysis. Three grams (0.2 Gm) of quinine was recovered from the liver. A report of the analysis of two of the "black pills" that were obtained from the family was as follows: apio none, safin none, oil none, ergotin, none, ferrous carbonate, mass, and nuxvomica, about one-fifth gram (0.01 Gm).

COMMENT

The gross and histologic changes in the kidneys coupled with the ammoniacal odor of the gastrointestinal mucosa warrant a diagnosis of severe hemoglobinuric kidney damage with uremia. The clinical symptoms and laboratory results support this view. The recovery of 3 grams (0.2 Gm) of quinine from the liver is significant, since there was no drug taken during the last week of life while the patient was in the hospital.

Quinine is a drug in common use. Small doses may produce swelling of the face and hands, rash, giddiness and ringing in the ears. Following the ingestion of huge amounts cinchonism may develop with nausea

Fig. 2—Medulla of kidney under medium power showing hemoglobin masses in the lumen of the collecting tubules. Frozen section. Hematoxylin eosin stain.

emesis, diarrhea, cardiorespiratory depression, prostration and collapse. Some of the latter symptoms were manifested in the case here described.

The following quinine medication is as of rare occurrence. This is

perhaps true of the ordinary case of cinchonism Mezger and Jesse² do not record its presence in two fatalities observed in infants, nor does Raven,³ who reports a death in a woman, aged 50, following an estimated dose of 200 grains (13 Gm) of quinine taken as a soporific.

However, according to Else Petri,⁴ who reviewed the literature on the toxicologic effect of quinine hemoglobinemia and hemoglobinuria do occur, but only under certain physical-chemical conditions of the blood. This has been observed occasionally in patients suffering from "blackwater fever" and in very rare instances in early pregnancy. The exact nature of the quinine hemolysis is not understood. Apparently a certain susceptibility to hemolysis must be present when quinine produces hemoglobinemia. Nocht and Kikuth⁶ have shown that very small quantities of quinine may facilitate the amoceptor hemolysis in animal experiments. Donath and Landstener⁷ assert that during pregnancy autohemolysins are formed by a gradual disintegration of a large number of red corpuscles. It is believed that women with eclamptic tendencies are especially susceptible to hemolysis.

Quinine does not exert a direct action on the kidneys. It is readily excreted by the gastro-intestinal tract and the kidneys very shortly after intake. When the hemoglobin, following hemolysis, reaches a sufficient concentration in the blood it is excreted by the kidneys, and hemoglobinuria is recognized. The kidney damage is due to the accumulation of hemoglobin in the tubules, with mechanical blocking of the urinary flow, increasing oliguria or complete anuria and uremia.

A review of the literature revealed a total of eight fatal cases bearing on the problem of our discussion. Seitz⁸ has reported three cases. A woman, aged 35 two months pregnant, was given three doses of 0.5 Gm of quinine every two hours. Within five hours the urine became dark red. Spectroscopic examination revealed oxyhemoglobin and methemoglobin. Marked anemia developed. The blood urea increased to 250 mg per hundred cubic centimeters. The patient died on the twelfth day. The cortex of the kidneys was a dirty grayish brown. A diagnosis of nephritis was made. His second patient, two months pregnant, showed excessive vomiting. She was given 1.5 Gm of quinine in an attempt to induce an abortion. Within two hours hemoglobinuria developed, followed by jaundice. Seitz believes this was due to a sudden hemolysis of red cells the resistance of which had been lowered by the pregnancy. No histologic changes of the kidneys were described. In the third case, 0.5 Gm of quinine was given in three doses to a woman three months pregnant and an abortion was produced. The patient voided black urine, which contained much hemoglobin but no red cells. Autopsy was not obtained.

Kutz and Traugott⁹ reported two cases. Their first patient was a woman, two months pregnant, in the state of abortion. She was given 0.4 Gm of quinine in two doses, nausea and cyanosis developed and she became

irrational. Much hematoporphyrin was found in the urine, which was a dirty black in appearance. Post-mortem observations were not conclusive. Thorough histologic examination of the kidneys was not reported. Their second case was similar to their first one.

Frommolt¹⁰ reported a case in which a criminal abortion had been performed and quinine injection, in unknown dosage, had been given. At autopsy the kidneys were a dark brownish red, and a diagnosis of hemorrhagic nephritis was made. The author reported a second similar case.

Petri⁴ described a case in which a woman of 26 had taken barbitol, and in addition 1 Gm of quinine each day for three days, at which time she died. Methemoglobinemia was noted clinically. Histologic examination of the kidneys showed hemoglobin masses in Bowman's capsules and in the lumens of the convoluted tubules. The tubules showed no epithelial damage.

Fig. 3—Kidney cortex under medium power showing granular and globular hemoglobin masses in convoluted tubules and loops of Henle. Capsules of Bowman are free. Note the focal interstitial inflammation in the upper left half of the picture. Paraffin section. Hematoxylin-eosin stain.

The eight patients who died after the administration of quinine were all in the early stage of pregnancy. In each case there was hemoglobinuria. Necropsy in seven instances demonstrated a marked renal lesion, which was diagnosed grossly as nephritis or hemorrhagic nephritis. In Petri's case alone there is an adequate histologic description of the hemoglobinuria, accompanied by a drawing.

Our case differs from that of Petri in that certain inflammatory changes developed in the kidneys in addition to the very marked hemoglobinuric infarcts present in large parts of the tubular system. This can be explained by the fact that at least seven days elapsed in our case between ingestion of the drug and the time of death. This time element may account for the severe degenerative epithelial lesions in the convoluted tubules in our case which were not present in Petri's case.

SUMMARY

1 A woman, approximately three months pregnant, had taken quinine, estimated as 100 grains (6.5 Gm.), and hemoglobinuria and uremia developed. The blood urea nitrogen reached 344 mg per hundred cubic centimeters.

2 In the kidneys there was found marked distention of the tubular system, brought about by masses of hemoglobin (so-called hemoglobinuric kidney damage), associated with definite focal inflammatory lesions.

3 Three grains of quinine was recovered from the liver.

HEART BLOCK AND PREGNANCY

REPORT OF A SUCCESSFUL DELIVERY

MITCHELL BERNSTEIN, M.D.

PHILADELPHIA

The problem of pregnancy in a patient with heart disease is always one of serious concern. Paul D. White¹ states that "the important question concerning heart disease in pregnancy is the prognosis, one of the most difficult problems in medicine." Should the gestation be terminated or should there be no intervention in a cardiac patient? Is there any assurance that in the gravid cardiac patient, with good cardiac compensation, heart failure may not develop later because of the added burden of pregnancy? When the heart disease is due to complete heart block and pregnancy supervenes, as in the case here reported, what procedure should be followed?

It is interesting to note that a study of the literature up to Jan. 1, 1936 yielded only six² recorded cases of complete heart block in which successful gestation had occurred. Herrmann and King³ reported one of these six cases. Their patient had had complete auriculo-ventricular heart block since the age of 20 and had had six successful deliveries without complications. The valvular damage had been slight, with evidence only of mitral insufficiency. Her heart rate was never over 40 per minute. She experienced no trouble in her six parturitions. With this very meager number of six cases one naturally would be hesitant in making a definite decision in a patient with heart block and pregnancy.

HISTORY OF HEART BLOCK

Cecil⁴ states that Morgagni in 1761 recorded the first case of heart block (Oslei), while the Irish physicians Robert Adams in 1826 and William Stokes in 1846 published clinical accounts of the disease, later to be known as Adams-Stokes' syndrome. Gaskell in 1881 introduced the term "heart block," while in 1893 His discovered and described the narrow band of neuromuscular tissue between the auricle and the ventricle—the auriculoventricular bundle.

SYMPTOMATOLOGY OF HEART BLOCK

Patients with complete heart block may be comparatively free from any subjective symptoms. On the other hand, symptoms may occur from time to time and vary from dyspnea, palpitation of the heart, fatigue and faintness to frequent attacks of severe vertigo, with marked slowing of the pulse from 25 to 30 per minute. Adams-Stokes' syndrome, i. e., syncope.

Fig. 1—An analysis of the curves showing a ventricular rate of 52 per minute with a slightly irregular rhythm. The auricular rate is 90 per minute, the rhythm being regular. Complete heart block is present and in addition left ventricular hypertrophy is indicated. Myocardial degeneration would be indicated by reason of the damage to the conduction system.

attacks with heart block, may supervene and add further to the gravity of the situation. In heart block when the ventricle stands still for more than ten seconds, the symptoms will be of a cerebral nature varying from giddiness to loss of consciousness. These symptoms disappear with the beating of the ventricle. Death

Fig. 2—Aug. 5, 1933 tracing taken immediately after delivery showing delayed conduction to 0.4 second.

however, may occur if the ventricular standstill is not interrupted after intervals of from ten to fifteen seconds.

PROGNOSIS OF HEART BLOCK

The existence of complete heart block usually implies severe and rather diffuse myocardial damage and hence grave disorder in the mechanics of the heart. Textbooks, in their descriptions of heart block, emphasize its peril and call attention to its not infrequent termination by sudden death. Mackenzie, cited by Cecil

⁵ Mackenzie James. Diseases of the Heart ed 4 London Oxford University Press 1925 p 260.

observed that the patient is often found dead in bed or elsewhere. Cecil⁴ remarks that patients with a mild form of heart block, even when the pulse rate is about 30, may lead quiet and uneventful lives for from ten to twenty years. Adams-Stokes' syndrome adds further to the peril. Sprague and White believe "the prognosis as regards life in the absence of marked demonstrable cardiac disease to be essentially good. The future, so far as the conduction defect is concerned, depends frequently upon an unknown factor and cannot be foreseen." In milder cases, no grave conditions arise from the delay or heart block itself.

Despite the usual grave prognosis of heart block, several authors have recorded cases of heart block of many years' duration in patients who have been relatively free from symptoms. Lewis⁶ states that heart block per se does not kill and that, although it is usually a sign of serious and often progressive myocardial damage, it may exist for some time, especially in young persons who are relatively and absolutely in good health. Smith⁷ reported a case of complete heart block of thirty years' duration with practically no difficulty or restricted activities. Ellis⁸ reported one case of heart block of twenty-four years' duration, two of nine years' duration, one of seven years' duration, all free from cardiac insufficiency. Willis⁹ reported a series of thirty-seven cases of complete heart block with an average duration of two and nine-tenths years, the longest duration being fifteen years. A case of intermittent heart block of twelve years' duration was reported by Russell-Wells and Wiltshire.¹⁰ White, through Ellis,⁸ reported two cases with complete heart block of fourteen and fifteen years' duration and yet free from cardiac symptoms. These two patients were quite well and led active lives.

Harris¹¹ reported a case in which heart block existed for twenty-eight years, and the patient had enjoyed good health during this time. In short, the prognosis in cases of heart block should be based on the condition of the myocardium together with a careful consideration of the etiologic factors involved. My patient evidenced no signs of cardiac failure despite the existence of heart block, a positive blood Wassermann reaction and a supervening pregnancy.

NATURE OF HEART BLOCK

Heart block, or auriculoventricular block, is a physiologic disturbance of the heart in which there is impairment of the conduction impulses from the auricles to the ventricles. The excitation wave in its spread from the time it leaves the sinus node until it reaches the auricular ventricular node of Tawara usually requires from 0.12 to 0.2 second, the latter being the upper limit of normal as recorded in the electrocardiogram. If the time interval is prolonged beyond 0.2 second the condition is known as "first degree heart block." Further involvement of the junctional tissue leads to second degree, or incomplete, heart block. Complete heart block exists when the electrocardiogram regularly shows ventricular complexes of slow rate,¹² which have no relation to the auricular activity. The ventricular

rate is usually low, about 40 or less per minute, but may rarely reach as high as 70, the auricular rate is usually higher than the ventricular, depending on the rate of the rhythm originating in the sinus node or on that of an auricular ectopic center, as in auricular tachycardia. The auricular rhythm may be completely irregular, as in auricular fibrillation, or rapid and regular as in auricular flutter.

CAUSES OF HEART BLOCK

Heart block may result in the course of acute inflammatory diseases, namely, diphtheria, influenza, rheumatic fever, endocarditis and nephritis. It may occur as a result of a chronic disease process involving the heart, such as syphilis. Vascular lesions such as arteriosclerosis involving the coronary arteries may lead to fibrotic, fatty and calcific¹³ changes of the nodes, the bundle of His, and the myocardium. Thrombosis or embolism of the coronary arteries with infarction of the interventricular septum may lead to complete heart block. Digitalis in toxic doses may produce complete heart block. Bacterial toxins in tetanus and in intestinal toxemias¹⁴ have been reported as causes. Heart block may also be of congenital, traumatic, senile or functional origin.

INCIDENCE OF HEART BLOCK

Sir James Mackenzie¹⁵ in 1925 wrote "Heart block is comparatively speaking a rare condition, but it is a subject of considerable importance in that it throws light upon vital processes which are present in every organ." He recorded observations in a series of patients with heart block and observed that "few people have the opportunity of seeing sufficient numbers of cases which illustrate all phases of the subject."

In the last fifteen years at the Massachusetts General Hospital,¹⁶ in an electrocardiographic series of 9,000 cases in which there were cardiac symptoms or signs, auriculoventricular block was diagnosed in 581 cases (6.5 per cent). It was complete in seventy-six, or 13 per cent, of these 581 cases and partial in 505 cases, or 87 per cent. However, no mention is made as to the percentage of males and females in this series.

In a series of 1,200 cases of all types of cardiac irregularities, Hamburger, cited by Cecil, noted that 9.6 per cent were due to all types of heart block. The types of block were: partial block, 3.1 per cent, bundle branch block, 2.8 per cent, delayed PR interval (first degree block), 2.5 per cent, and complete auriculoventricular block, 0.8 per cent.

In an electrocardiographic series of 3,000 cases reported by Lemann¹⁷ from the Touro Infirmary, there were thirty-eight cases of atrioventricular block, eleven of complete block, six of partial block, and twenty-one of delayed conduction time beyond 0.20 second. One of the complete blocks and one of the partial blocks occurred in patients aged 22 and 28 respectively.

Sprague and White¹⁸ reported eleven cases of high grade heart block with varying etiologic factors in patients under the age of 30.

Hence, in the total number of 13,211 cardiac patients studied electrocardiographically by the foregoing authors, there were 108 cases of complete heart block.

It has been estimated by White¹⁶ that about 90 per cent of the higher grades of block occurred in patients over 50 years of age, because of the greater incidence of coronary disease. Obviously, then, the possibility of pregnancy would be limited to the remaining 10 per cent of patients in the child-bearing period. The very few reported cases of heart block and pregnancy may be explained by the fact that not all cases of pregnancy are studied electrocardiographically and that these patients are younger than those in whom heart block usually develops.

REPORT OF CASE

C B, a married woman, aged 23, of Spanish descent, admitted Nov 16, 1931, to the Jefferson Medical College Hospital Dispensary in the service of the late Dr Thomas McCrae, complained of precordial pain with radiation to the left shoulder and left arm. The symptoms had existed off and on for about one year prior to admission. There was no definite history of diphtheria, influenza or rheumatic fever.

The patient was married at the age of 17 years and had had many miscarriages. Her mother died of "Bright's disease" and an aunt died of heart disease.

Examination of the patient November 16, was essentially negative except for the cardiac condition. The heart was slightly enlarged to the left. A cardiac arrhythmia existed, together with a slow heart rate varying from 40 to 50 per minute. A soft systolic murmur was audible at the cardiac apex. The blood pressure was 120 mm of mercury systolic and 80 mm of mercury diastolic. At subsequent examinations the bradycardia persisted, although occasionally the cardiac rate appeared to be normal.

Throughout the period of observation over three years, the patient's blood pressure varied from 98 to 110 mm of mercury systolic and from 55 to 74 mm of mercury diastolic. Wassermann tests of the blood were reported as plus four on several occasions.

Electrocardiographic study of the patient Nov 27, 1931, made by Dr Ross V Patterson, showed a ventricular rate of 47 per minute, with a slight irregularity and an auricular rate of approximately 88 per minute and regular. Complete auriculoventricular dissociation was present. Repeated examinations of the patient were made in 1932 but no evidence of cardiac decompensation was detected. Clinically the patient seemed rather comfortable, evidencing precordial distress only on occasions. Dr Patterson later reported the following electrocardiographic observations: Jan 22, 1932 the ventricular rate was 55 per minute and the auricular rate was 68 with complete dissociation. Both the auricular and the ventricular rhythms were regular. February 26 the ventricular rate was 50 per minute and the auricular rate 75 per minute, and a complete heart block was present.

Roentgen examination by Dr John T Farrell, February 3 showed that the heart was normal in appearance and its transverse diameter was not increased. It measured 12.5 cm, while that of the chest was 25 cm. The diaphragm was smooth and regular in outline. Subsequently roentgen examination on November 15 showed a moderate enlargement of the heart, the right ventricle being particularly involved, its diameter indicating moderate enlargement. The left ventricle was also very slightly increased in diameter over the normal.

Feb 2, 1933, the patient reported that she was pregnant and believed that she was at the fourth month. At that time physical examination showed no evidence of cardiac decompensation, although the cardiac impulse was visible and palpable 10 cm to the left of the midsternum at the fifth left interspace. Frequent examinations up to May 9 showed no marked changes in the patient's cardiac condition.

Electrocardiographic study, May 12 1933 was reported as follows. The auricular rate was 70 per minute there was uneven spacing of the ventricular beats, the time of individual beats, if continued, varying from 50 to 75 per minute. Complete dissociation was present. Antisyphilitic treatment, which had been instituted when the patient was first observed, was continued without a pause.

Clinically the patient appeared quite comfortable and despite the advanced pregnancy there were no apparent signs of decompensation.

Moreover, the original precordial pain for which the patient was admitted to the dispensary service, Nov 16, 1931, had apparently disappeared or at least was conspicuous by its absence.

Aug 4, 1933, the patient began active labor, being then at full term. She was admitted to the service of Dr P Brooke Bland at the Jefferson Medical College Hospital. After thirty-six hours of active labor without any apparent progress Dr Thaddeus L Montgomery delivered her of a living baby by cesarean section under local anesthesia. Immediately following delivery the cardiac rate was 40 per minute. The patient was discharged from the maternity after two weeks of an uneventful puerperium.

Further electrocardiographic studies by Dr Patterson, taken immediately after delivery, were as follows. August 5 the interval between auricular and ventricular contractions was the same and varied from 18 seconds to 12 seconds. The auriculoventricular conduction time was 0.4 second. Another record taken on the late afternoon of the same day showed regular rhythm of auricles and ventricles at 60 per minute, with the same auriculoventricular conduction time as before. August 8 the auricular and ventricular rates were 75 per minute and the conduction time was 0.4 second. August 9, the auricular and ventricular rates were 75 per minute, conduction time was 0.4 second. October 16, there was complete heart block. The auricular rate was 60 per minute and the ventricular rate 48 per minute.

Altogether, ten electrocardiographic studies were made on nine different dates, beginning Nov 27, 1931 and ending Oct 16, 1933. All showed complete dissociation of auricular and ventricular contractions, with the exception of two records on Aug 5, 1933, and one record each on Aug 8 and Aug 9 1933, in which there was delayed conduction without complete block. The last study, made Oct 16, 1933, showed a reversion to complete block.

Physical examination Oct 16, 1933, on several occasions during 1934 and again in January 1935 showed the patient to be free from any cardiac symptoms. She had gained some 15 pounds (6.8 Kg) since the birth of her child in August 1933.

HEART DISEASE AND PREGNANCY

Bland¹⁹ observes that "organic lesions of the heart wall or of its valves are sometimes seriously aggravated during pregnancy." Further, he states "The strain of labor does not interfere with cardiac function, so long as compensation is maintained, but the exertion of the second stage may occasionally prove disastrous in threatened or frank incompetency. The great danger under such circumstances is acute dilatation of the right heart and sudden death."

De Lee²⁰ states "My own experience has taught me to fear the complication of heart disease with pregnancy, for, even though one finally brings the patient through alive, the dangers that threaten at every step are very disquieting and when accidents do occur they require the promptest and most skilful treatment." De Lee further observes that "it is generally admitted that the heart is peculiarly liable to disease during gestation and that existing disorders are aggravated."

Pardee²¹ in an article on cardiac conditions indicating therapeutic abortion remarks

After 1924 the functional classification that had been introduced by the New York Heart Association was used in the cardiac antepartum clinic of the Lying-In Hospital for it was considered inadvisable to have one functional classification for cardiac patients who were pregnant and another for those who were not.

The basis of this functional classification is the patient's history of her ability to perform the ordinary physical activity

19 Bland P B and Montgomery T L. Practical Obstetrics for Students and Practitioners. Philadelphia F A Davis Company 1934 pp 71 and 144.

20 De Lee J B. Principles and Practice of Obstetrics ed 6 Philadelphia W B Saunders Company 1933 p 536.

21 Pardee H E B. Cardiac Conditions Indicating Therapeutic Abortion. J A M A 103 1899 1902 (Dec 22) 1934.

of her everyday life without unusual shortness of breath or palpitation. The patient's statements as to her ability to exercise are combined with an observation of the pulse rate and the respiratory reaction after a rather strenuous test exercise performed in the presence of the physician. According to the results of this method cardiac patients are divided into four categories as follows:

Class 1 Patients with heart disease who are able to undertake ordinary physical activity without discomfort, such as palpitation or dyspnea, and who perform the test exercise without unusual tachycardia or dyspnea.

Class 2A Patients whose ordinary activity is slightly limited because of the appearance of dyspnea, palpitation or fatigue, and who show somewhat excessive tachycardia and dyspnea after the test exercise.

Class 2B Patients whose activity is greatly limited because of the appearance of dyspnea or palpitation and who show marked tachycardia and dyspnea after the test exercise or who are unable to complete it.

Class 3 Patients whose activity is so limited as to make them unable to walk around without dyspnea or palpitation and who are so evidently dyspneic after such slight efforts as getting into and out of bed or walking across the room as to make any other exercise test unnecessary.

The foregoing classification, which is essentially that suggested in the Criteria for the Classification and Diagnosis of Heart Disease¹ has been the one I have used. The patient in this case was grouped in class 1 since she did not show physical signs of cardiac insufficiency or any discomfort after ordinary activity.

It is obvious that to the usual perils of pregnancy in the cardiac patient one must take into account in a case such as that just reported the superimposed dangers that may arise because of an existing heart block.

COMMENT

The etiology of the heart block in the case here reported is probably due to syphilis. Blood Wassermann tests were repeatedly plus four, while the history of the case failed to tell of any of the other causes of heart block.

Antisymphilitic treatment was instituted when the patient first came under my observation in November 1931 and was continuous through the gestation in 1933. Of special interest is the fact that the complete heart block was changed to delayed auriculoventricular conduction time of 0.4 second, Aug. 5, 1933, immediately following delivery. This persisted at least until August 9, as evidenced by the electrocardiograms. Later electrocardiographic studies showed a reversion to complete heart block.

CONCLUSION

Experience with this case of heart block and pregnancy in addition to the six similar cases reported by others, suggests that the gestation should not be interrupted if cardiac compensation maintains. Patients with heart block and pregnancy should be observed frequently. Electrocardiographic studies are advisable. Sufficient rest should be obtained by the patient, thus avoiding overexertion and cardiac decompensations. Prolonged labor should not be permitted, and delivery should be by cesarean section or by the use of forceps. Local or spinal anesthesia should be used.

There is no escape from the fact that pregnancy should be terminated if heart failure occurs in a gravid cardiac patient including heart block. Fortunately in the case here recorded there were no signs of decompensation during the period of gestation. Hence the patient was permitted to go to full term. The result justified the conservative measures.

1321 Spruce Street

THE EFFECT OF EPHEDRINE ON THE EMPTYING TIME OF THE HUMAN STOMACH

EDWARD J. VAN LIERE, PH.D., M.D.

DONALD H. LOUGH, B.S.

AND

CLARK K. SLEETH, B.S.

MORGANTOWN, W. VA.

Since the introduction of ephedrine for therapeutic use by Chen and Schmidt in 1924¹ it has been widely used in clinical medicine. It probably enjoys the greatest use in asthma, hay fever and hypotensive states. It is, however, used in many other conditions. Wood² found it of use in a case of Adams Stokes' syndrome, Doyle and Daniels³ reported its use in the treatment of narcolepsy, and Arnett⁴ reported using it in amylal poisoning. Other instances could be enumerated in which new uses have been found for this drug.

Considerable work has been reported on the effect of ephedrine on the gastro-intestinal tract. Kinnaman and Plant,⁵ working with unanesthetized dogs that had permanent gastric fistulas, observed that ephedrine relaxed gastric tone and inhibited motility. McCrea and MacDonald⁶ found that ephedrine inhibited gastric peristalsis and caused a fall in intragastric pressure in cats. Marcu and Savulesco,⁷ using the balloon method, found that minute doses of ephedrine caused transitory contraction but that larger quantities produced inhibition of gastric movements.

In view of these studies and since ephedrine is used so widely in medicine, it was thought well worth while to study its effect on the emptying time of the stomach in man.

METHOD

The normal emptying time of the stomach was ascertained fluoroscopically in six healthy young male subjects. The experimental meal was given at 8:30 a.m. No food had been taken since the evening before. The standard meal consisted of 15 Gm. of Quaker Farina. This was boiled in 350 cc. of water until it reached a total volume of 200 cc., 1 Gm. of salt was added for flavor and barium sulfate (50 Gm.) was added so that the contents of the stomach could be seen with the fluoroscope. Approximately eight control determinations of the emptying time of the stomach were made on each individual. The average of these figures was used for the control.

The effect of the ephedrine sulfate was now studied. One grain (0.065 Gm.) of ephedrine sulfate with about 3 ounces (90 cc.) of water was given about twenty minutes before the standard meal was eaten. The emptying time of the stomach was determined fluoroscopically as already described. Attention was given, of course, to all details that were essential for carefully controlled experimental conditions.

From the Department of Physiology, University of West Virginia. Aided by a grant from the Committee on Scientific Research of the American Medical Association.

RESULTS

The accompanying table and chart show the results obtained

The table shows that there is considerable variation in the normal emptying time of the stomach. The extremes were 1.03 hours and 2.80 hours. The average for the six individuals was 2.07 hours. It will be seen that ephedrine produced a marked effect on the emptying time of the stomach. In two individuals it was prolonged over 118 per cent and in no case was the prolongation less than 72.8 per cent. The average prolongation of gastric evacuation for the six individuals was 91.66 per cent.

The Effect of Ephedrine on the Emptying Time of the Stomach

Subject	Normal in Hours	Effect of Ephedrine in Hours	Delay Caused by Ephedrine in per Cent
1	2.17	3.75	72.80
2	1.94	4.37	125.30
3	1.03	2.21	118.40
4	2.50	4.50	80.00
5	2.02	3.62	79.40
6	2.80	4.67	74.10
Average	2.07	3.89	91.66

COMMENT

It is generally conceded that ephedrine has an action similar to that of epinephrine. The main difference is that the former has a much more sustained action. Both preparations stimulate the sympathetic nervous system. The sympathetic fibers to the stomach are carried by the splanchnic nerves. These fibers, when stimulated, inhibit stomach motility. It would be expected then that ephedrine would delay gastric evacuation.

Not only is ephedrine capable of stimulating the sympathetic fibers but it may also have a further action in that it may relax the smooth muscle. Chen and Schmidt⁸ reported that the effect of ephedrine on isolated muscle of the intestinal tract was inconstant but that it more frequently inhibited than stimulated. Swanson⁹ found that practically all the ephedrine-like compounds showed distinct inhibition of intestinal

movements. Balyeat and Rinkel¹⁰ reported that ephedrine may relax the bladder and give rise to urinary retention, in fact its use is suggested for nocturnal enuresis.

It may well be, then, that ephedrine has two distinct actions on the stomach, first it may stimulate the sympathetic fibers, which would cause diminished motility of the stomach, and, second, it may actually relax the smooth muscle directly.

Besides these modes of action of ephedrine its effect on the pylorus sphincter must be considered. As far as we are aware there is nothing in the literature that deals with the effect of ephedrine on the pylorus. Thomas,¹¹ however, has reported considerable work on the influence of epinephrine on the pyloric sphincter. He found that on the whole no pronounced changes in tonus of the pyloric sphincter were caused by epinephrine, it is apt to increase the tonus of the pylorus when the muscle is relaxed and may decrease the tonus when the muscle is contracted. It is possible, in lieu of these observations, that ephedrine may have caused a certain amount of increased tonus of the pyloric sphincter. It is very problematic in our judgment that this was an important factor in delaying the emptying time of the stomach. We feel that the real delay was caused by the factors already mentioned.

We wish at this point to emphasize the fact that the results reported in this paper may well have important clinical significance. If a patient, for example, is receiving ephedrine sulfate regularly for some chronic ailment such as a hypotensive state or asthma, there is every reason to believe that the emptying time of the stomach of such a patient would certainly be delayed. Furthermore in evaluating the experimental results obtained it is necessary to point out that the standard test meal used consisted practically of carbohydrates. This meal left the stomach quickly, as our control figures show. If, on the other hand a larger meal had been given containing not only carbohydrates but also fats and proteins and if we are allowed to assume that gastric evacuation would be proportionally prolonged, food would be retained in the stomach for a long time indeed.

The fact that ephedrine has such a marked effect on gastric motility makes it not unreasonable to suppose that ephedrine could cause a certain amount of stasis in the small and large intestine.

In view of the results reported in this paper it is suggested that the clinician pay considerable attention to the diet as well as to the elimination in patients who are receiving ephedrine regularly.

SUMMARY AND CONCLUSIONS

It was found that under carefully controlled conditions ephedrine sulfate in therapeutic doses, 1 grain (0.065 Gm.) prolonged the emptying time of the stomach in six healthy young male subjects. In the case of two individuals gastric evacuation was prolonged over 118 per cent. In no case was the prolongation less than 72.8 per cent. The average prolongation for the six individuals was 91.66 per cent.

In view of the fact that ephedrine is so widely used in more or less chronic conditions such as asthma, hypotensive states and hay fever, it is felt that the results reported in this paper are of interest to clinical medicine.

Clinical Notes, Suggestions and New Instruments

UNUSUAL ORIGIN OF A MECKEL'S DIVERTICULUM FROM THE BASE OF THE APPENDIX

M N HADLEY M D AND H D COGSWELL M D INDIANAPOLIS

Meckel's diverticulum, once considered a medical curiosity, has come to be recognized as a definite pathologic entity as the result of the abundance of literature that has appeared in late years. In the years 1930-1931 and the first half of 1932 fifty-six articles appeared in the literature of the different countries dealing with Meckel's diverticulum.¹

Lavater² in 1671 was one of the first to record a case of diverticulum of the terminal ileum. In 1707 an excellent illus-

Fig 1—A appendix B origin of the band of tissue that extended to the umbilicus C junction of the appendix and the diverticulum

tration of a diverticulum of this type was given by Ruysch.³ Morgagni⁴ discussed diverticula of the intestine in his treatises in 1809, but it remained for Meckel in the same year to advance the theory of its origin and to describe the condition more fully. There were only occasional reports of the complications arising from a Meckel's diverticulum until 1905, when Porter⁵ collected reports of 184 pathologic cases, stressing the importance of this embryologic remnant. Since that time there have been many reports published of the various anomalies and complications existing with a Meckel's diverticulum, but no record can be found similar to the case here recorded.

The distance that a Meckel's diverticulum is found from the ileocecal valve varies greatly. We have been unable to find a report of a diverticulum originating nearer to the ileocecal valve than 4 cm.⁶ Von Rokitsansky⁷ believed that it was 1 to 2 feet from the cecum. Cunningham's anatomy states that in a large series of autopsies the greatest distance was 12 feet and the smallest distance was 6 inches. In Christie's² series the site of the diverticulum varies from 6 to 36 inches.

The illustrations were made by Mr F. Glone and Mr H. Sahager from the division of general surgery, Indiana University School of Medicine.

REPORT OF CASE

This case is presented because of the unusual location of a Meckel's diverticulum.

History—M. L., a white boy, aged 9 years, entered the James Whitcomb Riley Hospital Aug. 1, 1934, complaining of pain in the right lower quadrant of the abdomen, nausea and vomiting. The past history was irrelevant except for the usual diseases of childhood. The family history revealed that the patient had had a younger brother who died of intussusception at the age of 9 months. The boy had been feeling well until the day before admission to the hospital. On the morning of July 31 he had been walking stooped over and, on questioning, his mother found that he was having pain in the right lower quadrant. He was given magnesia magma and by noon he had vomited and was crying with pain. That evening he was given another laxative and he slept poorly.

Examination—The physical examination showed right rectus rigidity, rebound tenderness, pain and tenderness over McBurney's point, a mass about the size of a plum was palpated in this area. Laboratory studies revealed a normal urinalysis, normal red blood count and hemoglobin, the white blood count was 12,450, with 38 per cent polymorphonuclears, 1 per cent basophils, 12 per cent lymphocytes, 2 per cent myelocytes, 2 per cent metamyelocytes and 45 per cent band cells. The Wassermann reaction was negative.

Operation and Course—A preoperative diagnosis of acute appendicitis was made, and the abdomen was opened through a McBurney incision. Lying lateral to the cecum, a discolored sausage shaped mass was found (fig. 1), which originated from the base of the appendix and proved to be a diverticulum of the appendix. At the distal end of the mass there was a band of tissue containing a few small blood vessels which ran medial and was attached to the underside of the umbilicus. This band was ligated and cut. The appendix was then ligated and amputated.

The pathologic condition was evidently due to the rotation of this diverticulum from a medial position to its lateral position in relation to the cecum. This produced a torsion in the appendix, obstructing its lumen and causing a circulatory disturbance, which was responsible for the acute condition found.

The patient made an uneventful convalescence and left the hospital August 11. Pathologic examination by Dr. C. G. Culbertson revealed that the gross specimen consisted of an appendix and 1.5 cm. from the base of the appendix, a large

Fig 2—The diverticulum opened and a probe introduced from the diverticulum to its opening into the appendix.

diverticulum which was cylindric and measured approximately 9 cm. in length. At the distal end of the diverticulum was a ligated cylindric cord which was said to be attached at the distal end to a region near the umbilicus. No structure resembling a peptic ulcer was present. The appendiceal attachment of the diverticulum was split open, and it was seen to have a small lumen which was continuous with the lumen of the appendix.

A section of the wall of the diverticulum showed on microscopic examination the peritoneal layer and the subperitoneal

layer to be edematous and to be diffusely infiltrated with lymphocytes, plasma cells and eosinophils. Both muscular coats showed leukocytic infiltration. The mucosa was that of the large intestine. The lining epithelium of the mucosa was ulcerated in many places and contained polymorphonuclear leukocytes. A section of the structure that connected the diverticulum with the umbilicus showed only a mass of fibrous tissue containing numerous veins and arteries.

COMMENT

The unusual location of this diverticulum can be better understood if the embryology of its formation is considered.

The yolk sac in the human embryo develops early, and at the end of the second week is a sac with a wide opening into the intestine. During the third week the yolk sac becomes somewhat constricted off, remaining connected, however, with the lumen of the intestine by a pedicle, called the yolk stalk or vitelline duct.

Fig. 3—Loop of intestine and umbilical coelom with the yolk stalk still intact. Anlage of cecum.

The yolk stalk is attached to the intestine a short distance from the stomach in the primitive gut, which at this early stage forms a simple tube of uniform diameter extending from the stomach to the caudal end of the embryo. A portion of the gut then forms a loop, the apex of which extends into the umbilical coelom and is attached to the yolk stalk (fig. 3). Soon after the loop is formed, a small evagination appears in the descending portion of the loop, not far from the apex. This is the anlage of the cecum.⁸ This anlage for a time continues to increase uniformly in size, then the proximal end increases more rapidly than the distal and forms the cecum. The distal end, failing to keep pace in development, remains slender and forms the vermiform appendix.

Usually at the time that the anlage of the cecum can be defined, the yolk stalk becomes reduced to a cord of cells in the umbilical cord and separates from the loop of gut. In a small percentage of cases that portion of the yolk stalk lying between the intestine and the umbilicus fails to degenerate and is then known as a Meckel's diverticulum. This marks the position of the original 'apex' of the umbilical loop.⁹

Evidently, in this case, the yolk stalk at the apex of the umbilical loop, was attached to that area of gut where the anlage of the cecum was to make its appearance. During the

development of the appendix and cecum this was at the distal end of the anlage, so that at the end of their development the diverticulum was present at the base of the appendix.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

HOWARD A. CARTER, Secretary

AMERICAN UNIVERSAL DESK ACCEPTABLE

Manufacturer: American Seating Company, Grand Rapids, Mich.

The desk considered by the Council is recommended for use in schools and colleges. It consists of (1) the Better-Sight desk top (type E), (2) the Standard desk top (type S), and (3) the seat accompanying both desk tops. This acceptance does not include other furniture manufactured by this firm, for example, seats for use in the theater, church and business establishments.

THE BETTER-SIGHT (TYPE E) DESK TOP

The Better-Sight (type E) desk top consists of a steel frame book box with a level cover strip carrying inkwell and pencil trough, and a lid attached, forming the desk. Arrangements are made whereby the lid may be adjusted at various angles.

THE STANDARD OR TYPE S DESK TOP

The Standard or Type S desk top of the American Universal Desk is identical with the Type E or Better-Sight desk top except for the attachment for tilting the desk lid. The desk top is fastened with hinges to the level strip at the front of the desk for the purpose of making the interior of the box accessible.

This desk top is designed for use in the primary grades where protracted reading and writing with their postural and visual implications are not the major type of school activity, and where large type books, fundamental arm and hand movements and manipulative activities prevail.

SEAT OR CHAIR

The seat or chair member of the Universal Desk consists of a maple seat form with moderate slope and shallow saddle-form scoop having no rim or elevation rearward of the sitting area. The back consists of a fixed upper and an oscillating lower rail. The lower rail automatically adapts itself to the form of the back in contact with it and is rounded on the lower edge, as is the upper rail on the upper edge. Seats are made in three sizes and are adjustable as to height.

CLAIMS

The major claims made for the American Universal Desk are (1) that it is so constructed that even when used unintelligently or carelessly it cannot be conducive to bad posture, eye strain or other harm; (2) that operation is either automatic or so easy and obvious that it will not fail to function through neglect or ignorance; and (3) that construction has been subjected to such severe tests of durability and has been so designed that little in the way of repairs from defective operation need be anticipated.

In a very large measure the Better-Sight desk top combined with the chair member may be expected to lessen eye strain and to encourage a good sitting posture.

The desk was examined carefully by investigators of the Council and was found to be comfortable and believed to be admirably adapted to the conservation of vision.

In view of the favorable report, the Council voted to include the American Universal Desk for school use in its list of accepted devices.

Council on Pharmacy and Chemistry and Committee on Foods

The Council on Pharmacy and Chemistry and the Committee on Foods of the American Medical Association record with deep sorrow the death, Dec 9, 1935, of

LAFAYETTE BENEDICT MENDEL

Born at Delhi, N Y, Feb 5, 1872, Professor Mendel was graduated from Yale University in 1891. He became interested in physiology and physiologic chemistry as a student under Prof. Russell H. Chittenden and received the degree of Doctor of Philosophy in that department of study in 1893. After a period of study and travel abroad he returned to Yale where he achieved conspicuous success as a teacher. He was appointed professor of physiologic chemistry in 1903, and in 1920 he was appointed to the newly created Sterling professorship, which position he held up to the time of his death.

As an investigator his interest was chiefly in the field of nutrition, and his wide reputation in that field grew in large measure out of his joint contributions with Dr. Thomas B. Osborne of the Connecticut Agricultural Experiment Station, where for many years, and until his death, he was associate biochemist. These outstanding biologic studies revealed wide differences between various proteins in the alimentation of animals and brought to light many hitherto obscure facts concerning the role of amino acids, vitamins and inorganic constituents in the phenomena of growth and nutritional well being. He published alone or with associates nearly 300 scientific papers and in addition wrote many editorials, reviewed many scientific books and made numerous popular addresses. His essays "Childhood and Growth," "Changes in the Food Supply and Their Relation to Nutrition" and "Nutrition, the Chemistry of Life" are in book form. Professor Mendel's familiarity with scientific literature, his command of English and his unusual powers of exposition enhanced the force of his scientific works and gave them literary charm.

In an advisory and consulting capacity he served his university on numerous departmental boards and committees among them the Board of Permanent Officers of the Yale Graduate and Medical schools and the Governing Board of the Sheffield Scientific School. During the World War he gave generously of his time to various activities under the auspices of the Department of Science and Research of the Council of National Defense and as a member of the Interallied Scientific Food Commission.

Professor Mendel was keenly interested in the chemical aspects of problems in medicine, and in 1934 the New York Chemists Club awarded him the Conne medal for his outstanding contributions in that field. This interest together with his profound knowledge of physiologic chemistry and nutrition made his service to the Council on Pharmacy and Chemistry and to the Committee on Foods of the American Medical Association, of inestimable value. He served the Council for eighteen years and the Committee from the beginning of its work and he served both with characteristic interest and loyalty.

Abundant and deserved recognition came to him in the form of academic honors, citations by learned societies, and recognition by industrial and trade associations of national scope thus indicating at once the wide appreciation of his scientific achievements and the breadth of his interests.

On his sixtieth birthday former students of Professor Mendel presented him with a portrait of himself done by John Quincy Adams. This testimonial of regard and affection suggests those finer attributes of the man himself which impressed his pupils, his colleagues and his friends, and which are aptly described by his contemporary, Dr. Graham Lusk, who has said of him:

"He has been the guide, philosopher and friend to many young men and women. He has encouraged them to walk by themselves when they were able to stand alone and he has given wise counsel in times of difficulty. Herein he has shown himself as one of the great teachers of his time."

His colleagues on the Council and the Committee will remember him for his high ideals of service, his vision and his knowledge, but they will cherish his memory no less as a wise and sympathetic counselor and loyal friend, who commanded their confidence and won their esteem.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary

JELKES GOOD LUCK BRAND EVAPORATED MILK

Distributor—John F. Jelke Company, Chicago

Packer—United Milk Products Company, Elkhorn, Wis.

Description—Unsweetened sterilized evaporated milk

Manufacture—Milk received from company inspected farms is tested for bacteria count, sediment, temperature, odor and flavor. Methylene blue tests are made regularly. The milk is preheated to 100 C., partially evaporated, homogenized, cooled to 2-4 C., standardized to conform with U. S. Dept. of Agriculture standard, filled into cans, sterilized and immediately cooled.

Analysis (submitted by manufacturer) —	per cent
Moisture	74.2
Total solids	25.8
Ash	1.5
Fat (ether extract)	8.0
Protein (N × 6.38)	6.4
Lactose (by difference)	10.5

Calories—1.4 per gram, 40 per ounce

Claims of Manufacturer—See announcement of acceptance of Evaporated Milk Association, Educational Advertising (THE JOURNAL Dec 19, 1931, p. 1890)

CELLU JUICE-PAK PINEAPPLE JUICE

Distributor—The Chicago Dietetic Supply House, Inc., Chicago

Packer—Hawaiian Pineapple Co., Ltd., San Francisco, California

Description—Hawaiian pineapple juice retaining in high degree the natural vitamin content.

Manufacture—The method of manufacture is essentially the same as for Paradise Island Brand Hawaiian Finest Quality Pineapple Juice (Unsweetened) (THE JOURNAL June 3, 1933, p. 1769).

Analysis (submitted by distributor) —	per cent
Moisture	85.3
Ash	0.4
Fat (ether extract)	0.3
Protein (N × 6.25)	0.3
Reducing sugars as invert sugar	8.6
Sucrose (copper reduction method)	3.7
Crude fiber	0.02
Carbohydrates other than crude fiber (by difference)	12.8

ALLERGY, IMMUNITY AND THE TUBERCULIN REACTION

At this time respiratory disease occupies more than its usual share of clinical attention. The differentiation of tuberculous from nontuberculous pulmonary diseases becomes of increasing importance. The recent communication of Dr Myers¹ in THE JOURNAL justly and properly focuses attention on the tuberculin reaction and its genesis, course and significance. In the past it was generally assumed that a positive Mantoux test signified immunity (as well as allergy) to the tubercle bacillus and conversely that a negative test meant lack of infection, lack of allergy and absence of immunity. Experimental evidence now shows convincingly that this visible reaction is not a necessary concomitant of immunity and that the latter can function fully and effectively in the complete absence of evidence of this hypersensitivity.² Further, it has even been shown that the allergic necrotizing-inflammatory response, far from being helpful or protective, may even be injurious.³ The so-called anergic, or nonreactive, phase has long been known—a negative response in the presence of highly active or overwhelming infection. These investigations and others tend to refute the frequently heard contention that a negative tuberculin test means absence of immunity. It is not improbable that an early infection even without the almost inevitable subclinical reinfections may leave an immunity lasting long after the positive skin test has completely disappeared or at least defies detection.

Much of our present information is empirical and, in making any empirical study,⁴ clearly understood and

uniform criteria are prerequisite. The absence of such criteria in clinical investigations of tuberculosis has been an obstacle to more rapid progress. The possibility that various observers are seeing different forms of tuberculosis in their respective localities is another hindrance. Erythema nodosum is such an example. Workers in tuberculosis in the United States and other sections of the Western World see less erythema nodosum than their clinical colleagues in Europe and the Old World. Further, there is no general agreement that its etiology is tuberculous. Though most investigators feel that it is an allergic manifestation of some sort, its true nature as yet unknown. Nor should we allow ourselves to be lulled into an attitude of false security by such apparently satisfying terms as resistance and immunity. These are merely relative. The course of any infection is determined by the size and virulence of the infecting inoculum and by the state of the host's immunity or resistance (be it inherent or acquired, active or passive) and is to a large extent conditioned and modified by the degree of activity of his specific hypersensitive state. The activity of the latter is known to fluctuate unpredictably and may depend largely on the factor of time alone. Allergy to the tubercle bacillus may last a lifetime (the result of how many subclinical reinfections we have no way of knowing), whereas allergy to a micro-organism such as the pneumococcus is quite short lived. The state of resistance, however, is much less easily ascertained, some estimate can frequently be made from the individual history, from the racial and constitutional type, and occasionally from immunologic and bacteriologic laboratory studies. All too commonly, survival from infection is its only real measure.

Finally, then, on what is the diagnosis of tuberculosis to be made? The finding of a negative response to tuberculin will rule out tuberculosis as the basis of certain clinical disorders, whereas a positive test means only that the hypersensitivity is present.⁵ In each instance the possible relationship of this hypersensitivity to the disease under observation still remains to be proved. The tuberculin test is of definitely limited value. No test or method will supersede the painstaking study of the individual patient. This together with the recognition of the ever present possibility of tuberculous infection will allow few cases to go undiscovered. An upper lobe pneumonia that resolves with abnormal slowness or incompletely or a long standing "postinfluenzal asthma with low grade fever" is at times explained with extraordinary ease by a careful search of the sputum or the roentgenogram of the chest. If each patient is to get the best management and if we are to maintain the advances made against the ravages of the "white plague," we cannot afford to relax vigilance.

THE IODINE REQUIREMENT OF MAN

The importance of iodine in human nutrition and the relation of this element to hypertrophy of the thyroid gland were suggested in the earliest medical writings. It has been stated¹ that the Chinese knew of the beneficial effect of substances now known to be rich in iodine many centuries before the time of Christ and that the feeding of the ash of the sponge, also known to contain large amounts of iodine was a common treatment for goiter at the time of Hippocrates and Galen. Similar accounts appear in early American literature. In a "History of the White Mountains," Mrs. Lucy Crawford² refers to the frequency of enlargement of the thyroid gland in natives of Coos County, N. H. at the close of the seventeenth century and relates how her grandfather brought sea salt a bushel at a time, 80 miles over the mountains on his back. The suggestion that the chemical element iodine itself was effective in the treatment of goiter was made in 1820 by Comdet,³ only nine years after the discovery and isolation of iodine as a chemical entity by Courtois. Soon after this in 1833, iodized salt was suggested for the prevention of goiter by the young French chemist Boussingault.⁴ The effectiveness of iodine in the control of goiter was largely discredited at the time of these reports and not until 1895 when Baumann⁵ actually demonstrated the presence of iodine in the thyroid gland, was the relationship unequivocally established.

As in the case of other elements and substances necessary for human welfare questions soon arose regarding the amount of iodine needed to meet the daily human requirement. Information in this direction has been secured by the use of the well known nutritional device the method of 'balance' determinations, in which the amounts of the substance in question that are excreted and retained are determined in subjects ingesting varying quantities. The first comprehensive study of this type on iodine⁶ indicated that a normal adult human subject remained in positive iodine balance when as little as 17 micrograms of the element was consumed in the daily diet. Approximately 84 per cent or 14 micrograms of the ingested iodine was excreted. It is of some interest that considerable amounts of iodine, from 10 to 15 per cent of the total were excreted in the sweat and nasal secretions and that approximately 80 per cent appeared in the urine and from 5 to 10 per cent in the feces. As might be expected, there was an increased excretion of iodine in subjects consuming larger amounts of the element, a

maximum retention of approximately 20 micrograms was observed. Similar results have been recorded in a series of twelve normal subjects ingesting from 54 to 155 micrograms of iodine daily⁷ and, more recently,⁸ on two normal individuals consuming 56 and 156 micrograms, respectively, of iodine each day. Unfortunately, in the latter study the amount of iodine excreted in the sweat was not determined. From the data recorded in the foregoing investigations it appears that the daily iodine retention in normal individuals consuming varying amounts of this element does not exceed between 15 and 25 micrograms, thus indicating that the actual requirement of the normal human adult probably does not exceed 25 micrograms daily. Undoubtedly the suggested value of 50 micrograms daily as the amount that should be present in the human dietary allows a satisfactory margin of safety.

In patients with certain diseases of the thyroid gland there appear to be significant variations from the normal in the excretion of iodine. In cases of hyperthyroidism with or without goiter, for example, there is a marked increase in the amount of iodine excreted daily in the feces.⁹ It has also been stated that there is an increased loss of iodine in the sweat of patients with hyperthyroidism.¹ Changes such as these in the excretion of iodine in diseases of the thyroid gland are of singular interest and merit further thorough investigation.

CUMULATIVE ACTION OF DIGITALIS
GLUCOSIDES AND CARDIAC
NECROSIS

The persistent action of digitalis suggested long ago an accumulation of the drug in the body. The selective action on the heart and blood vessels indicated possible selective distribution of the digitalis to these organs. Straub¹ developed evidence of such selective action of strophanthin in the frog ventricle. Later, however, Weese² showed that not more than 9 per cent of digitalis glucosides accumulate in the mammalian heart. The content of digitalis in the heart decreased as other organs, such as the kidney and liver, were added to a heart-lung system. Weese concluded that the distribution of digitalis was largely extracardial, a view supported by demonstration of a concentration of the drug in the liver and other viscera of digitalized birds, reported by Hanzlik and Wood.³

Textbooks, however, have continued to record the clinical impressions of cardiac accumulation and have supported these with the original experimental results

of Hatcher⁴ who studied the cumulative action in cats by his method of determining the fractional fatal dose necessary to kill after variable periods of medication. Since the cause of death was cardiac, the close association of cardiac accumulation and fatal dose appeared natural and conclusive. The theory of this procedure postulated only the chemical fate of the drug. It failed to take into consideration such effects as sensitization, desensitization and injuries that might be caused by the drug and the effects of these changes on successive doses of digitalis. This procedure has been questioned by German investigators and the so-called cumulative action is shown to be essentially a reaction of the injured heart resulting from the digitalization.

For instance, Bauer⁵ reports that digitalis and strophanthin cause typical necrotic changes in the hearts of cats treated with high doses of these drugs. The effects are of two kinds: reversible and irreversible, largely according to the result from the first dose. The outcome can be predicted in from two to four days after the first dose. If the heart is accelerated and its rhythm disturbed, the outlook is unfavorable because the second dose of digitalis for fatal effect will be small. But, if the heart action is normal the second dose will be high. Atropinization does not alter the outcome. Strophanthin requires about 25 per cent higher doses than does digitoxin. The "cumulative" effects are to be looked for in the pathologic changes in the heart muscles, especially the papillary muscles and trabeculae. Dogs and rabbits do not show the "cumulative" actions and also do not show the necrotic changes in the heart.

The pathologic changes, which are described by Buchner⁶ consist of loss of nuclei from the cardiac muscle cells, leukocytic infiltration, cloudy swelling and degenerative processes—a picture of microscopic necrosis. Evidences of healing are strands of connective tissues, which replace the injured cardiac muscle. According to Buchner, the morphologic changes in the hearts of digitalized cats are not unlike those of clinical coronary disease. The necrotic changes of ischemia are suggested. Possibly they are the result of coronary contraction or of a direct action on the muscle cells, as digitalis is both a vasoconstrictor and an irritant. Whatever is the correct explanation, further tests by Weese and Kieckhoff,⁷ with heart-lung preparations of digitalized cats demonstrate that cardiac function is impaired. Provisionally, the German reports cast a doubt on the validity of the fractional fatal dose method of Hatcher for determining cumulative actions of digitalis and its allies.

Whether the reported functional and morphologic injuries in the cat heart occur in clinical digitalization is not known. Species differences are indicated by the apparently negative results with dogs and rabbits. Nevertheless, it has been asserted that clinical reactions to digitalis resemble the actions in cats. Spontaneous repair and reversibility of the cardiac processes suggest that permanent damage to a heart may not occur with ordinary therapeutic administrations, which are generally interrupted or periodic. Microscopic necrosis from the action of digitalis may be less serious than are the changes in an abnormal heart for which the digitalis is given. However, a pathologic or decompensated heart may be more readily injured by digitalis than is a normal heart. Actually, some clinicians feel that the wrong use of digitalis does little or no permanent good and may eventually do harm. These opinions are apparently not based on demonstrated pathologic changes in human hearts. Hence it would seem advisable to make clinical observations along these lines.

Current Comment

HORMONES AND NITROGEN METABOLISM

The internal secretion of the thyroid gland exerts a profound regulatory effect on metabolic processes. One of the most striking is the production of a distinct negative nitrogen balance. It has been observed, however, that the degree of negative balance is quite variable. As yet, a satisfactory explanation for the inconsistency has not been made. There are suggestions that the hormone of the adrenal cortex may likewise be involved in the maintenance of nitrogen balance. For example, in patients with Addison's disease a negative nitrogen balance exists, which becomes positive when adequate amounts of adrenal cortex extract are administered. A recent experimental study¹ adds further evidence to support the view of a relationship between adrenal cortical hormone, thyroxine and nitrogen metabolism. The nitrogen balance of adrenalectomized dogs was determined during control periods and periods during which either or both adrenal cortex extract and thyroxine were administered. A negative balance was sometimes observed in the animals that did not receive adrenal cortex extract or else received sub-maintenance doses, when thyroxine alone was given, consistent negative balances were found, as might be expected. The simultaneous administration of adrenal cortex extract with thyroxine, however, definitely lessened the degree of nitrogen loss. If sufficiently large doses were used, a positive balance sometimes could be obtained. Thus it appears that the amount of cortical hormone which is available is one of the factors that condition the amount of nitrogen catabolism induced by the hormone of the thyroid and that the cortical hormone exerts a protective action against the effect of thyroxine. This alleged relationship would afford another example of the antagonistic activity of the hormones in the regulation of body processes.

Association News

RADIO BROADCASTS

The American Medical Association broadcasts over WEA, the Red network instead of the Blue, as formerly, and certain additional stations of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time 2 o'clock Pacific time) each Tuesday, presenting a dramatized program with incidental music under the general theme of 'Medical Emergencies and How They Are Met'. The title of the program is 'Your Health'. The program is recognizable by a musical salutation through which the voice of the announcer offers the toast 'Ladies and gentlemen, your health'. The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

Red Network—The stations on the Red network of the National Broadcasting Company are WEA, WEEL, WTIC, WJAR, WTAG, WCSH, KYW, WFBR, WRC, WGY, WBEN, WCAE, WTAM, WWJ, WMAQ, KSD, WHO, WOV, WDAF.

Pacific Net coil—The stations on the Pacific network are KGO, KPO, KFI, KGW, KOMO, KHQ, KFSD, KTAR.

The next three programs are as follows:

February 18 Heart Disease Morris Fishbein M.D.
February 25 Crippled Children W. W. Bauer M.D.
March 4 Cancer W. W. Bauer M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Plans for a Speakers' Bureau—Plans are now being made to establish a speakers' bureau for the Arkansas Medical Society, in accordance with action taken at a recent meeting of the council. Dr. Darmon A. Rhinehart, Little Rock, chairman, public relations committee is in charge of the arrangements, and it is believed that the bureau will be functioning before the next annual session in April. Societies wishing to use the facilities of the bureau are asked to communicate with Dr. Rhinehart.

Society News—The Fifth Councilor District Medical Society was addressed at Eldorado January 7, by Drs. George R. Livermore and J. H. Eugene Rosamond, Memphis, on diseases of the prostate and earache in children respectively. At a meeting of the Mississippi County Medical Society in Blytheville January 7, Drs. Lemly L. Hubener and Dyess discussed 'The Choice of Obstetric Instruments and the Method of Application' and Floyd Webb Blytheville 'Middle Ear Infection'. Dr. Charles R. Rountree, Oklahoma City, addressed the Miller County Medical Society recently on 'Fractures In and Near the Elbow Joint'. The Benton County Medical Society was addressed January 9 by Dr. Guy Hodges, Rogers, on 'Bronchopneumonia in Childhood'.

CALIFORNIA

Society News—Dr. Stanley Cobb Bullard, professor of neuropathology, Harvard Medical School, Boston, discussed 'Epilepsy and the Causes of Convulsions' at a joint meeting of the Los Angeles Society of Neurology and Psychiatry and the internal medicine section of the Los Angeles County Medical Society, February 10.

Food Poisoning from Imported Antipasto—The California State Department of Health announces a recent outbreak of food poisoning traced to imported antipasto. The department states that this is the second outbreak of food poisoning

attributed to this product within the last few years. An effort is now being made to determine whether the infected product has been widely distributed over the state.

COLORADO

Society News—The Colorado Hospital Association will hold its annual meeting April 28-29 this year, instead of in the fall as in previous years. A symposium on disorders of the parathyroid gland was presented before the Medical Society of the City and County of Denver, February 4, by Drs. Thaddeus Sears, William C. Black, Kenneth D. A. Allen, Wilfred S. Dennis, Roy P. Forbes and William W. Haggart.

Annual Registration Due Before March 1—Every person licensed to practice any form of the healing art in Colorado is required by law to register annually before March 1 with the secretary-treasurer of the Board of Medical Examiners and to pay a fee of \$2 if a resident of Colorado or \$10 if a non-resident. Failure to pay this fee within the time stated automatically suspends the right of a licensee to practice while delinquent. If he nevertheless continues to practice he is subject to the penalties provided by law for practicing medicine without a license. Failure to pay this fee for three consecutive years results in the automatic cancellation of a delinquent practitioner's license to practice.

DISTRICT OF COLUMBIA

Annual Graduate Clinic—The fourth annual graduate clinic of George Washington University School of Medicine will be held at the University Hospital, February 29, with the following program:

Dr. Frederick A. Reuter: Analysis of Routine Examination of the External Genitalia.
Dr. Joseph Lawn Thompson: Unusual Case of Meningococcus Septicemia.
Drs. Paul T. Dickens and Charles S. White: Observations on Total Thyroidectomy for Congestive Heart Failure and Angina Pectoris.
Dr. Howard T. Kane: Obstetric Analgesia.
Dr. Walter Freeman, represented by Dr. Hyman D. Shapiro: Outpatient Treatment of General Paralysis of the Insane with Malaria.
Dr. Jacob Kotz: Treatment of Functional (Endocrine) Disorders in Females.
Dr. Daniel L. Borden: Emergency Use of Murphy Button.
Dr. Harry H. Donnelly: Acute Purulent Pericarditis in Infancy.
Dr. Radford Brown: Endometriosis.
Dr. Paul S. Putzki: Carcinoma of the Rectum.
Dr. Harry A. Davis: Use of Fluids in the Treatment of Shock.
Dr. Raymond W. Murray: Treatment of Dyspepsia.
Dr. Paul F. Dickens: Treatment of Nephritis.
Dr. William Leroy Dunn: Treatment of Angina Pectoris.
Dr. Howard T. Kane and staff: Use of Paraldehyde in Obstetrics.

GEORGIA

Society News—Dr. Calvin B. Stewart presented a paper on 'Cancer Prevention' before the Academy of Medicine, Atlanta, January 16. Dr. James J. Clark discussed 'Interlobar Lesions and Their Correct Diagnosis,' and Dr. Richard B. Wilson presented a case report of carcinomatosis of the meninges. All are from Atlanta. Speakers before the Fulton County Medical Society, February 6, included Dr. Leila A. Daughtry-Denmark, Atlanta, on 'A Study in Whooping Cough Immunization and Diagnosis'.

Personal—Dr. Charles W. Folsom, formerly health officer in Knox County, Ky., has been appointed to a similar position with the Walker-Catoosa County Health Department, succeeding Dr. Samuel P. Hall Jr., who resigned. Dr. Charles A. Greer was recently reelected mayor of Oglethorpe for the twentieth term. Dr. Robert Frank Cary, Monticello, has been elected health officer of Terrell County, with offices in Dawson. Dr. Henry Grady Callison has been named health commissioner of Augusta and Dr. William A. Mulhern chairman of the board.

ILLINOIS

New Buildings for Manteno State Hospital—As a part of an extensive building program at the Manteno State Hospital, Manteno, contracts have been let for twelve ward buildings, diagnostic building, hospital for the tuberculous, two hydrotherapy wards, mechanical building and two dormitories for employees. The total amount to be expended will be about \$3,700,000 with contracts calling for completion of the work by December 15. Most of the buildings which were erected under this program last year at a cost of \$1,900,000 are now occupied and include six ward buildings, hospital building, store building and laundry. A general kitchen was completed, as well as the installation of mechanical equipment. With the additions, the bed capacity of the hospital has been increased by 1,600.

Society News—At a meeting of the Adams County Medical Society in Quincy, February 10, Dr Frank Smithies Chicago, spoke on ulcerative lesions of the intestine—Dr Porter P Vinson, Rochester, Minn, discussed "The Newer Findings in Pulmonary Disease with the Use of the Bronchoscope" before the Peoria City Medical Society, February 4—At a meeting of the St Clair County Medical Society in Belleville, February 5, Dr Charles H Eyermann, St Louis, discussed "Allergy in General Practice," and Dr Rolland L Green, Peoria, president-elect, state medical society, February 6, in East St Louis, social aspects of medicine—Dr Joseph Brennemann, Chicago, addressed the Sangamon County Medical Society, February 6, in Springfield, on "Pneumonias of Childhood"—The Springfield Medical Club, Springfield will be addressed March 17 by Dr Anton J Carlson, Chicago, on "The Control of the Endocrine Glands"

Chicago

Meeting on Industrial Medicine—The Central States Society of Industrial Medicine and Surgery met jointly with the Chicago Medical Society, January 15 Speakers included

Dr John J Moohead New York Traumatic Surgery Trends
Dr George G Davis Problem of the Pneumoconoses in Industry
Dr Allan J Hruby Clinical Aspects of Pulmonary Fibrosis Produced by Dust Diseases
Dr Henry C Sweany Pathology of the Pneumoconoses
Dr Hollis E Potter, Roentgenologic Visualization of Lung Fibrosis Produced by Silicosis and Other Dusty Occupations
Daniel D Carmell assistant attorney general of Illinois The Legal Status of Occupational Diseases in Illinois
Dr Philip H Kreuscher The Role of the Medical Department of the Illinois State Industrial Commission in Connection with Occupational Disease

Society News—The Chicago Medical Society will be addressed, February 19, by Dr Wilburt C Davison, dean, Duke University School of Medicine Durham N C, on 'Brucellosis' Dr Williams McKim Marriott, dean, Washington University School of Medicine, St Louis, will speak on 'Hypoglycemic Reactions in Childhood, and Dr Nathan B Van Ethen, New York speaker, House of Delegates, American Medical Association 'Economic Problems of Interest to the Medical Profession' A symposium on syphilis was presented before the society, February 5, by Drs Harold A Rosenbaum, Oliver S Ormsby and George W Hall—Dr Owen H Wangersteen, Minneapolis, discussed "Intestinal Obstruction" before the Englewood branch of the Chicago Medical Society January 7

INDIANA

Personal—Dr Sherman S Frazier Angola has been appointed secretary of the Angola City Board of Health to succeed the late Dr P Norman Sutherland who held the position for more than twenty-five years—Dr Alva L Spinning, Covington, has been appointed health officer of Fountain County

Society News—Dr William R Cubbins, Chicago, discussed "Fractures of the Elbow and Knee Joints" before the Fort Wayne Medical Society, February 3—Dr Lindon Seed Chicago, discussed hyperthyroidism before the Montgomery County Medical Society in Crawfordsville, January 30—At a meeting of the Knox County Medical Society in Vincennes, January 21, Dr Warren W Hewins, Evansville spoke on prostatic disease and transurethral prostatectomy—Dr Thurman B Rice, Indianapolis, addressed the Jasper-Newton County Medical Society in Kentland January 31 on Health Fads—Dr Robert M Moore, Indianapolis, addressed the Tippecanoe County Medical Society, February 11, in Lafayette on diseases of the coronary arteries—Dr Henry F Beckman, Indianapolis, discussed "Toxemia of Late Pregnancy" before the Northwestern Indiana Academy of Medicine, January 30

IOWA

Personal—Dr Mark C Wheelock, formerly on the staff of the state hospital at Cherokee has been named assistant superintendent of the state hospital in Mount Pleasant—Dr Wayne J Foster, Cedar Rapids, has been appointed to the board of control in athletics at the University of Iowa Dr Foster is a graduate of the State University of Iowa College of Medicine Iowa City, and a former athlete

Society News—Dr Edward A Schumann Philadelphia discussed "Ectopic Pregnancy" before the Des Moines Academy of Medicine and the Polk County Medical Society, February 7—The Linn County Medical Society will be addressed in Cedar Rapids, March 12, by Drs William E Brown on "Physiology of the Uterus in Labor" Charles Sumner Day "Pathology of the Uterus in Labor" James Stuart McQuiston, "Movement Disorders and Various Types of Gaits" and Benjamin F Wolverton, "Practical Application of Electrocardiography" All speakers are from Cedar Rapids

KANSAS

New Medical Bureau—The Medical Credit Service Bureau of the Sedgwick County Medical Society was opened February 1, with Mr Harry A McGinley as manager At present only members of the society will be entitled to make use of the bureau, although later the facilities may be extended to members of the Wichita Dental Society and local hospitals

Society News—The Wyandotte County Medical Society was addressed, February 4, by Drs Harold V Holter on "Treatment of Puerperal Sepsis" and Eldon S Miller, 'Carotemia' Dr Harry R Wahl conducted a pathologic conference Speakers, January 20 were Drs Maurice A Walker and Harold L Ganey on 'Surgery and Diabetes' and "Pelvic Inflammation and Sedimentation" respectively A pathologic conference was also conducted by Dr Wahl—At a meeting of the Saline County Medical Society and the Golden Belt Medical Society in Salina, January 9, speakers were Drs Maurice Snyder, Salina, on "Simple Achlorhydric Anemia" Lucien R Pyle, Topeka, "Common Pathological Conditions of Pregnancy", Charles C Dennie, Kansas City, "Heat Treatment in Syphilis" and Harry L Smith, Rochester, Minn, "Syncope of Patients with Hypersensitive Carotid Reflexes" Syncope Attacks Reproduced by Pressure on the Carotid Sinus

KENTUCKY

Outbreak of Meningitis—Schools in five districts of Harlan County were closed by health authorities, February 7, when several deaths and more than twenty cases were reported in an outbreak of meningitis Cumberland, Lynch, Benham, Walhins and Shields were placed under quarantine As precautionary measures, health officers posted rules prohibiting more than three persons in stores at a time, closed all theaters and canceled all public gatherings, the Chicago Tribune reported

Bills Introduced—H 487 proposes to enact a new pharmacy practice act Among other things, the bill proposes to prohibit the sale, except on the prescription of a licensed physician dentist or veterinarian of hormones (synthetic or otherwise) barbital sulfonethymethane (trional), sulfonmethane (sulfonal), diethylsulfon, diethylmethane (tetronal) carbromal, paraldehyde chloral or chloral hydrate, chlorbutanol, all serums and antitoxins and the following emmenagogues or abortives: tansy, pennyroyal, rue, savin ergot and cotton root H 535 proposes to make incurable insanity on the part of either spouse a ground for divorce H 574 proposes to enact a new pharmacy practice act Among other things the bill proposes to prohibit the sale, except on the prescription of a legally qualified physician, of tansy, pennyroyal, rue, savin, ergot or cotton root

MARYLAND

Dr McCollum Awarded Medal—Elmer V McCollum, Ph D, professor of biochemistry and head of the department Johns Hopkins University School of Hygiene and Public Health, Baltimore, has been presented with the Callahan Memorial Award by the Ohio State Dental Society The award is a gold medal given each year to a person who has made a contribution to dental science which is of very exceptional value" Dr McCollum's research has dealt principally with nutrition

Cancer Clinics—A series of clinics on cancer planned by the Medical and Surgical Faculty of Maryland, opened at the University Hospital, Baltimore January 15 The clinics which are designed to acquaint practicing physicians with the latest developments in the prevention and diagnosis of cancer will be offered at the City Hospital, March 10 on surgical and radiation treatment of cancer April 29, in conjunction with the annual meeting of the faculty, on the cancer problem, May 21 at Johns Hopkins Hospital on surgical pathology of cancer A clinic was held in Salisbury, February 5, and one is planned for Cumberland, April 3

MASSACHUSETTS

New Health Commissioner for Boston—Dr William Basil Keeler, medical inspector for the South Boston health unit has been appointed health commissioner of Boston, succeeding the late Dr Francis X Mahoney Dr Keeler graduated from Tufts College Medical School in 1903 According to the *New England Journal of Medicine*, Dr Keeler was assistant to Dr Charles F Wilinsky deputy commissioner of health, with the assignment as medical inspector for the South Boston health unit

Psychiatric Awards—The New England Society of Psychiatry at its next spring meeting will make two awards, one of \$50 and one of \$25, to the writers of the best papers completed or published during the calendar year 1935 embodying

research in psychiatry by a younger worker. Physicians, psychologists, social workers or others are eligible and membership in the society is not a requisite. Writers who have once received an award are not again eligible. Seasoned writers, senior physicians or heads of departments in which there are junior workers while not inevitably excluded, will not generally be regarded as eligible for the awards. The work on which the papers are based should preferably have been done in New England or by workers now living in New England. Copies of articles or marked copies of journals in which the articles appeared should be sent before March 1 to the secretary of the society, Dr Harlan L. Paine, North Grafton.

Society News—Clarence W. Muehlberger, Ph.D., Chicago, gave a lecture at Harvard Medical School, February 6, on 'Some Newer Techniques in Medicolegal Investigation'. At the annual meeting of the New England Ophthalmological Society, January 21, Dr. William D. Rowland discussed "Simple Technique for Plotting Diplopia," and Dr. Francis Heed Adler, Philadelphia presented a paper entitled "Interpretation of the Different Forms of Tuberculosis of the Uveal Tract."—Dr. L. Emmet Holt Jr., associate professor of pediatrics, Johns Hopkins University School of Medicine, Baltimore, addressed the William Harvey Society at Tufts Medical School, February 13 on "Significance of Fats in Nutrition." Dr. Hiram Houston Merritt addressed the society, January 10, on Syphilis of the Nervous System.—Edgar Allen, Ph.D., New Haven, Conn., discussed "Reactions to Ovarian Hormones" before the Harvard Medical Society, January 28, in Boston.

Dr. Hunt to Retire from Harvard—The retirement of Dr. Reid Hunt, since 1913 professor of pharmacology at Harvard Medical School, Boston, has been announced, effective in September. Dr. Hunt is 65 years of age. He graduated from the University of Maryland School of Medicine in 1896 and after two years as tutor in physiology at the College of Physicians and Surgeons (Columbia), New York, served at Johns Hopkins University School of Medicine until 1903 as associate and as associate professor of pharmacology. He was chief of the division and professor of pharmacology of the U. S. Public Health Service from 1904 until 1913. In 1923 he was visiting professor to Peking Union Medical College and from 1920 to 1930 president of the U. S. Pharmacopeial Convention. He was chairman of the Section on Pharmacology and Therapeutics of the American Medical Association in 1908-1909, a member of the House of Delegates in 1911-1912 and has been a member of the Council on Pharmacy and Chemistry of the Association since its inception in 1905. He succeeded Dr. George H. Simmons as chairman of the Council in 1927. His investigations have been of the first order and have found ready recognition both in America and in Europe and he has contributed much to the literature on his specialty. Dr. Hunt's plans for the future were not announced.

MICHIGAN

Industrial Hygiene Laboratories—The Industrial Hygiene Laboratories of the Chrysler Corporation, Detroit, began operation January 1 under the direction of Dr. Stuart F. Meek, Detroit, as industrial hygienist and Gordon C. Harold as chemist. These laboratories located at the Dodge main plant of the Chrysler Corporation are devoted to the study of occupational diseases and their sources, together with other agencies and conditions of work leading to industrial health hazards. They have been planned under the direction of Dr. Crev. P. McCord, Cincinnati, who remains associated in the capacity of consultant.

Personal—Dr. Irmel W. Brown has been named director of the health department of Kalamazoo, succeeding Dr. John L. Lavan, resigned.—An enlarged photograph of an oil painting of the late Dr. Charles Godwin Jennings has been presented to the Wayne County Medical Society by associates and friends of Dr. Jennings.—Dr. William H. Pickett, Saginaw, has resigned as health officer of Saginaw County to accept a similar position in Florida.—Dr. Howard H. Cummings has been appointed assistant director of the postgraduate department, University of Michigan Medical School, Ann Arbor; he will serve on a part time basis, it is reported.

Society News—Dr. Henry W. Meyerding, Rochester, Minn., addressed the Gogebic County Medical Society recently on "Volkmann's Ischemic Contracture as a Complication of Fractures of the Elbow."—The Wayne County Medical Society was addressed December 16 in Detroit, by Mr. John D. Dingell, Detroit member of the U. S. House of Representatives and Dr. Roscoe L. Sensemich, South Bend, Ind., on the political and social aspects of the practice of medicine. The society was addressed January 6 by Dr. Walter M. Simpson,

Dayton, Ohio, on 'Artificial Fever Therapy' and Mr. Charles F. Kettering, director, General Motors Research Laboratories, 'The Engineering Aspects of the Apparatus Used for Artificial Fever Production'.

MINNESOTA

The Jackson Lecture—The third annual Clarence Martin Jackson Lecture was given by Dr. Russell L. Haden, Cleveland, February 5, at the University of Minnesota School of Medicine. His subject was 'The Human Red Blood Cell.' The Jackson lecture was established by Phi Beta Pi Medical Fraternity in honor of Dr. Jackson, who is head of the department of anatomy at the medical school.

Personal—Mr. R. R. Rosell, formerly field representative of the National Food Bureau, has been appointed assistant to the secretary of the Minnesota State Medical Association. Dr. Edward A. Meyerding, St. Paul. Mr. Rosell will keep in touch with negotiations in all parts of the state with county commissioners and relief officers in the conduct of medical care for the indigent and unemployed.—Dr. James C. Masson has been appointed chief of the surgical staff of the Mayo Clinic, succeeding the late Dr. Edward Starr Judd.

MISSISSIPPI

Bills Introduced—S. 105 proposes to create a state board of cosmetic therapy or beauty culture and to regulate the practice of cosmetic therapy or beauty culture. Among other things, such practitioners are to be permitted to remove superfluous hair. S. 110 proposes to enact a podiatry practice act and to authorize the state board of medical examiners to examine and license persons applying for licenses to practice podiatry. Such practitioners are to be authorized to diagnose and treat medically, mechanically, electrically, and surgically minor ailments of the human foot such as corns, calluses, warts, ingrowing and abnormal nails, bunions and similar conditions, and they are to be permitted to use such mechanical appliances as may be deemed necessary for the relief or cure of such ailments, except that they are to be denied the right to amputate the foot or toes, or to use anesthetics other than local. They are specifically prohibited from treating diseases and conditions of the feet produced by kidney, heart or other systemic diseases, unless they do so under the direction of a regularly licensed physician.

MISSOURI

Society Favors Abolishing Marine Hospital—In a resolution adopted January 28 the St. Louis Medical Society expressed its opposition to the expenditure of funds for the rebuilding of the local marine hospital and recommended its abolishment. The resolution explained that since the policy is to build marine hospitals where private hospital care is less economical, the society believes private hospitals in St. Louis could care for patients receiving treatment by the U. S. Public Health Service at less cost than a government hospital.

Cancer Control Meetings—The Holt County Medical Society and the Mound City chapter of the Twentieth Century Club sponsored a cancer control meeting at Mound City, January 7. Speakers included Drs. Henry J. Ravold and Harold E. Petersen. The St. Louis County Medical Society held a similar meeting in Clayton, January 22. Dr. Richard S. Weiss, St. Louis, discussed Precancerous Dermatoses and Dr. Louis H. Jorstad, St. Louis, Cancer of the Lip and Buccal Cavity, Prevention and Therapy. The cancer committee of the state medical association furnished the speakers for these meetings.

NEW YORK

Bills Introduced—S. 829 proposes to grant to charitable hospitals and to city and municipal hospitals treating persons injured through the negligence of others, liens on all rights of actions, claims, judgments or compromises accruing to injured persons by reason of their injuries. S. 764 to amend the law authorizing the formation of nonprofit hospital service corporations to render hospital services to their subscribers or members and to exempt such corporations from the provisions of the insurance laws proposes to extend the provisions of that law to a nonprofit service indemnifying corporation for the purpose of establishing, maintaining and operating a nonprofit service plan whereby policy holders shall be indemnified for amounts paid out or agreed to be paid out by them for medical and surgical care and treatment, nursing care and hospital care. S. 765 and A. 920 propose to authorize hospitals, supported in whole or in part from public funds or exempt from taxation, to employ physicians under a contract or salary arrangement for the treatment and care of patients who are a public charge. In all other cases the bill proposes, medical diagnosis and/or

treatment must be rendered to patients independently of other hospital charges and under contractual relationship between the patient and the physician. A 864 and A 865 propose to establish a board of chiropractic examiners and to regulate the practice of chiropractic, defined as "the adjusting by hand only of the articulations of the human vertebral column where misalignment or subluxations appear," and excluding "operative surgery, prescription or use of drugs or medicine, or the practice of obstetrics, except that the X-ray may be used solely for purposes of examination."

Pneumonia Control Program—A special program for the control of pneumonia was inaugurated January 1 by the state department of health in cooperation with the Medical Society of the State of New York, the State Association of Public Health Laboratories, the Commonwealth Fund and the Metropolitan Life Insurance Company. The division of laboratories and research distributed Dec. 30, 1935, a supply of concentrated type I antipneumococcus serum to seventy supply stations throughout the state. Under the direction of Dr. Edward S. Rogers, formerly of the staff of Massachusetts General Hospital, a special unit has been added to the division of communicable diseases which will devote its efforts to cooperation with the medical profession and evaluation of the results of the campaign. Facilities for typing sputum by the rapid Neufeld method are now available in seventy-seven approved laboratories throughout the state and it is planned to extend this service to place typing facilities within reasonable access of physicians in all parts of the state. The state medical society through its committee on public health and medical education of which Dr. Thomas P. Farmer, Syracuse, is chairman, is sponsoring special meetings and conferences of physicians devoted to the various aspects of pneumonia. Dr. Russell L. Cecil, New York, is chairman of a subcommittee on pneumonia directly in charge of this work. In addition, a number of official and volunteer nursing organizations are considering ways to provide adequate nursing service. As part of the campaign, Governor Lehmann issued a proclamation January 15 urging citizens to join in an effort to reduce the number of pneumonia cases and deaths "by disseminating knowledge of prevention through simple health rules and prompt action in securing early diagnosis and treatment where pneumonia is suspected."

New York City

Personal—Dr. Isidore H. Goldberger was not elected president of the Bronx County Medical Society, as noted in THE JOURNAL, January 4, page 49, but of another society with a similar name.

Fifth Harvey Lecture—Dr. John Farquhar Fulton, Sterling professor of physiology, Yale University, New Haven, will deliver the fifth Harvey Lecture at the Academy of Medicine, February 20. His subject will be "Interrelation of Cerebrum and Cerebellum in the Regulation of Somatic and Automatic Functions."

Tuberculosis Sanatorium Conference—A clinical session on chronic pulmonary diseases was held at Cornell University Medical College, February 5 by the Tuberculosis Sanatorium Conference of Metropolitan New York, under the auspices of the New York Tuberculosis and Health Association. Speakers, all of the staff of Seaview Hospital, Staten Island, included:

- Drs. David Ulmar and Oscar Auerbach: Clinical Course and Post-mortem Examination (presentation of cases)
- Drs. David Reisner and Iekoussiel C. Tchertkoff: Cystic Disease of the Lungs
- Dr. Henry K. Taylor \ Ray: Diagnosis of Pathology in the Larynx and Trachea
- Drs. George G. Ornstein and Pol N. Coryllos: Management of Bilateral Pulmonary Tuberculosis

Dr. Coryllos also spoke on "Closed Pneumolysis Indications and Management."

Alumni Day—Alumni Day of the New York University College of Medicine will be held February 22. The program will consist of papers and laboratory demonstrations, exhibits and ward rounds in Bellevue Hospital. Luncheon will be served at the college and the annual alumni dinner will be at the Park Central Hotel. Dr. John H. Wyckoff, dean, will give the address of welcome, and Dr. Walter Lester Carr, president of the alumni association, opening remarks. Others on the program will include:

- Dr. Irving Graef: Change of Structure in the Kidney as Related to Certain Changes in Function
- Dr. George B. Wallace: Action of the Mercurial Diuretics
- Dr. Meredith F. Campbell: Pyuria in Children
- Dr. Albert A. Epstein: Nephrosis
- Dr. Edward B. Gresser: Eye Changes in Nephritis
- Dr. Samuel Standard: Salt and Water Metabolism
- Dr. Homer W. Smith: The Biology of Excretion
- Dr. William Goldring: Urinary Findings in Renal Disease

Dr. Isaac Seth Hirsch and Robert Chambers, Ph.D., will participate in the demonstrations.

Record Low Death Rate—New York's mortality rate in 1935 was 9.9 per thousand of population, the lowest ever registered, according to the annual report of the health commissioner, Dr. John L. Rice. Four other death rates reported were said to be the lowest the city has had: infant mortality, 47.6 per thousand births; diphtheria, 0.9 per hundred thousand of population; typhoid, 0.5 per hundred thousand; and pulmonary tuberculosis, 52.2 per hundred thousand. The total number of deaths was 75,057. There were only 66 deaths from diphtheria in comparison with 210 in 1932, 37 from typhoid compared with 64 in 1932, and 3,969 from tuberculosis compared with 3,997 in 1932. Deaths from pneumonia have dropped from 9,245 in 1931 to 6,381 in 1935, appendicitis from 1,149 in 1933 to 921 in 1935. Suicides decreased from 1,595 in 1932, the highest point in the last ten years, to 1,147 last year. There were 2,134 cases of poliomyelitis in 1935, about half the number in the epidemic of 1931 and less than one fourth the number in the epidemic of 1916, the mortality rate was less than 5 per cent, much lower than in previous outbreaks. The birth rate was 13.2 per thousand of population, the lowest birth rate ever recorded in the city.

OHIO

Lectures on the Filtrable Viruses—Dr. Thomas M. Rivers of the Rockefeller Institute for Medical Research, New York, will deliver the Rachford Memorial Lectures at the University of Cincinnati College of Medicine February 27-28. His subject will be "The Filtrable Viruses."

Society News—Dr. Edward William Alton Ochsner, New Orleans, addressed the Academy of Medicine of Cincinnati, February 4, on "Treatment of Ileus Occurring Postoperatively and in Association with Peritonitis." Dr. John J. Shea, Memphis, Tenn., addressed a joint meeting with the Cincinnati Dental Society, February 11, on "Management of Fractures of the Superior Maxilla Extending Into the Alveolar Process."

OKLAHOMA

Society News—Speakers before the Tulsa County Medical Society, January 13, were Drs. E. Rankin Denny, on "Diabetic Coma," Gregory A. Wall, "Oblique Inguinal Hernia," and David V. Hudson, "Results in the Treatment of Syphilis in the Clinic." Dr. Leon H. Stuart addressed the society, January 27, on "Roentgen-Ray Treatment of Infections."

PENNSYLVANIA

Personal—At a meeting of the Lawrence County Medical Society in New Castle February 6, Dr. John P. Griffith, Pittsburgh, discussed differential diagnosis of acute conditions of the abdomen. Dr. James L. Gilmore, Pittsburgh, addressed the Fayette County Medical Society at Uniontown, February 6, on "Diagnosis and Treatment of Obstetric Problems." Dr. Hamlin C. Eaton has resigned as clinical director of the Warren State Hospital, Warren, to accept a similar position at the Polk State School, Polk. Dr. Eaton was secretary of the Warren County Medical Society for seven years.

Philadelphia

Changes in City Health Department—Dr. William C. Hunsicker has been appointed director of health of Philadelphia and Dr. Alfred F. Allman, assistant director. Dr. Hunsicker graduated from Hahnemann in 1895 and had been a member of the state senate for a number of years, resigning to accept the new position. Dr. Allman, a graduate of Jefferson Medical College in 1895, had previously been associated with the health department and at one time served on the city council. Dr. Martha Tracy, dean of the Woman's Medical College of Pennsylvania and Dr. Joseph C. Doane, medical director of the Jewish Hospital, have been appointed to the board of health to succeed Dr. James M. Anders, who resigned, and the late Dr. Ellwood R. Kirby.

"Professional Day" Celebrated—Dr. William B. Castle, associate professor of medicine, Harvard Medical School, Boston, received the Procter Award and new research laboratories were dedicated at the Philadelphia College of Pharmacy and Science as features of "Professional Day," January 31. Dr. Castle made an address on "New Developments in Products for the Treatment of Pernicious Anemia," E. Fullerton Cook, Ph.D., chairman of the U. S. P. Committee of Revision, discussed the new Pharmacopoeia, Adley B. Nichols, B.Sc., secretary of the Committee of Revision of the National Formulary, discussed the Formulary, and Dr. Horatio C. Wood, Jr., professor of pharmacology at the school, the use of official medicines in medical practice. The new laboratories are a memorial to Prof. Joseph Price Remington, presented to the school by Mr. Josiah K. Lilly and Mr. Eli Lilly, Indianapolis.

graduates of 1882 and 1907 respectively. An afternoon program was presented with the following members of the faculty as speakers: Arthur Osol, B Sc, on "Newer Chemical Aspects of the Pharmacopeia"; Louis Gershenfeld, P D, "Official Biological Products and the Official Preparations for Parenteral Administration"; Marin S. Dunn, Ph D, "Official Requirements for Vegetable and Animal Drugs"; Arno Viehoever, F C, "Biological Methods for Standardizing Cathartics," and Ivor Griffith, Ph M, "The Pharmacy of the U S Pharmacopeia."

SOUTH CAROLINA

Bills Introduced—H 1500 proposes to require as a condition precedent to the issuance of a license to wed that both parties to the proposed marriage present a certificate from a physician that they are physically and mentally fit to contract matrimony. S 1112 proposes to require the board of regents for the state hospital at Columbia to establish a department for the restraint and care of inebriates defined to be persons habitually so addicted to alcoholic drinks or the use of narcotic drugs as to be proper subjects for restraint, care and treatment. Probate judges are to be authorized to commit, on petition of interested persons, persons whom they determine to be inebriates to this department for restraint and treatment. S 1119 proposes to authorize the city council of any municipal corporation of more than 5,000 and less than 10,000 inhabitants which has acquired, constructed or caused to be constructed a hospital to establish a city hospital commission to operate and manage the hospital.

TENNESSEE

University News—Dr Henry E. Sigerist, William H. Welch professor of the history of medicine, Johns Hopkins University School of Medicine, Baltimore, lectured at Vanderbilt University School of Medicine, Nashville, in December on "Medicine in the Renaissance," "Medical Organizations in Europe" and "Life and Work of Louis Pasteur and Robert Koch."

Society News—Dr George D. Boone, Paris, among others, addressed the Carroll, Henry and Weakley Counties Medical Society in December on "Collapse Therapy in Tuberculosis." Drs. Nicholas S. Walker, Dyersburg, and Richard C. Newkirk, Tiptonville, among others, addressed the Dyer, Lake and Crockett Counties Medical Society January 1, on "Perinicious Vomiting of Pregnancy" and "Rachitic Pelvis" respectively. At a meeting of the Robertson County Medical Society in La Follette in December Drs. William P. Stone and Ernest W. Adair, Springfield, spoke on blood dyscrasias and on treatment of varicose veins. The Memphis Society of Ophthalmology and Otolaryngology held its annual "Clinical Day" in December in honor of Dr. Edward C. Ellett. The program consisted of demonstrations of operative procedures followed by a banquet at the university club in the evening at which Dr. Ellett made an address.

VIRGINIA

Bills Introduced—S 151 and H 234 to amend the law granting liens to hospitals treating persons injured through the negligence of other persons, on all rights of action, claims, judgments and compromises accruing to the injured persons by reason of their injuries, proposes to grant these liens also to physicians and nurses.

WEST VIRGINIA

State Laboratory Limits Free Work—The hygiene laboratory of the West Virginia Department of Health will henceforth limit its free work under a ruling of the Public Health Council, effective January 1, to charity cases properly certified by both patient and physician work of health agencies and state institutions, and work of private physicians of a public health nature. No specimen will be accepted for diagnosis except from a physician, and no reports will be given out except to physicians. It is believed that this policy of turning away from the state laboratory to private laboratories all specimens for which payment should be made will stimulate the establishment of more private laboratories meeting standard requirements. Specimens that should be sent to private laboratories include blood specimens for the purpose of obtaining licenses as in the case of barbers and beauticians who are required by law to present the report of a blood test annually. The only exception to this is made when the applicant and the examining physician sign a statement that the former is unable to pay for the laboratory examination. Since the ruling states that any specimen is considered of private

nature when a fee is charged for laboratory diagnosis, specimens from patients who are able to pay are to be sent to private laboratories, except when they are for the specific purpose of diagnosis, treatment and control of communicable diseases that affect the health of the public.

PHILIPPINE ISLANDS

Society News—A League of Medical Associations of the Philippines was recently formed by the Philippine Islands Medical Association, the Colegio Medico-Farmacaceutico de Filipinas, the Philippine Federation of Private Practitioners and the Philippine Public Health Association. Dr. Jose Fabella, commissioner of health and welfare, was elected chairman of the council of the league and Dr. Antonio S. Fernando, secretary. The league planned a national congress to consider health problems of the new commonwealth to take place early this year. At a recent meeting of the Manila Medical Society speakers were Drs. Alfredo Pio de Roda on "Action of Bacteriophage in Various Types of Staphylococci" and Eusebio Y. Garcia, on "Possibility of Predetermination and Control of Sex in Man by Electrical Methods."

GENERAL

Heart Journal Becomes Monthly Publication—Beginning with the January issue, the *American Heart Journal* will be published monthly instead of bimonthly as heretofore. The announcement was made on the tenth anniversary of the publication of the journal.

Orthopedic Examination—The next examination of the American Board of Orthopaedic Surgery will be held at Kansas City May 11. Applications to take the examination should be filed with the secretary, Dr. Fremont A. Chandler, 180 North Michigan Avenue, Chicago, on or before April 1.

Physical Therapy Meetings—The fifteenth annual scientific and clinical session of the American Congress of Physical Therapy will be held at the Waldorf-Astoria, New York, September 7-11. The midwestern section will hold its meeting at the Mayo Clinic, Rochester, Minn., March 4-5 and the southern section in New Orleans, March 23.

Society News—The twenty-second annual observance of National Negro Health Week sponsored by the U. S. Public Health Service, will be March 29 to April 5. The special objective for 1936 is "The Child and the School as Factors in Community Health." The American Laryngological, Rhinological and Otolaryngological Society will hold its annual meeting in Denver, May 18-20.

News of Epidemics—Two deaths from meningitis occurred in January at the Soldiers' Home Hospital, Sandusky, Ohio. A case in Topeka, Lawrence County, Miss., caused the county health officer to quarantine the community; it was reported January 25. A boarding house in Caretta, W. Va., was placed under quarantine January 10, after an inmate had become ill of meningitis. Nineteen cases and five deaths were reported in New York City for the week ended January 25. Wellsville, N. Y., was placed under quarantine in January after an outbreak of scarlet fever involving thirty-six cases and two deaths up to January 13. Schools were closed in two communities in North Union township in Pennsylvania the week of January 13 because of an epidemic of scarlet fever; eighteen cases were reported at that time.

Medical Bills in Congress—*Change in Status*. H. R. 10919 has been reported to the House, making appropriations for the Treasury and Post Office Departments for the fiscal year ending June 30, 1937. For the Bureau of Narcotics, an appropriation of \$1,275,000 is proposed. For the United States Public Health Service, the following appropriations among others are proposed: \$8,000,000 to assist states, counties, health districts and other political subdivisions of the states in establishing and maintaining adequate public health services including the training of personnel for state and local health work; \$1,155,160 for investigations of diseases and sanitation; \$64,000 for maintaining the National Institute of Health; \$5,870,000 for the pay of personnel and maintenance of hospitals; \$663,220 for the Division of Mental Hygiene, including the maintenance and operation of the Narcotic Farm, Lexington, Ky. The bill proposes that on and after July 1, 1936, the Narcotic Farm at Lexington, Ky., shall be known as the United States Public Health Service Hospital, Lexington, Ky. *Bills Introduced*. H. R. 10547 introduced by Representative Carmichael, Alabama, proposes to increase the lump-sum payment made under the federal employees' compensation act for death or permanent total or permanent partial disability suffered prior to Feb. 12, 1927. H. R. 10851, introduced by Representative Mahon, Texas,

proposes to authorize \$1,050,000 to erect a 300 bed hospital in west Texas for veterans H R 10933, introduced by Representative Stefan, Nebraska, and H R 10984 introduced by Representative Dirksen, Illinois, propose to make it unlawful to sell certain spirits containing alcohol produced from materials other than cereal grains

FOREIGN

Society News—The ninth French Congress of Stomatology will be held in Paris, October 5-10, under the presidency of Dr A Pont, Lyons Information may be obtained from the secretary general, Dr M Dechaume, 182 rue de Rivoli, Paris —Dr M E Binet, Vichy, France, is in the United States to invite physicians to attend an International Congress on Hepatic Deficiency, to be held in Vichy, Sept 16-18, 1937, under the presidency of Prof Maurice Loeper, professor of clinical medicine, University of Paris—The International Congress for Experimental Cytology will be held in Copenhagen, probably during August Members and others who may be interested are requested to submit to the committee suggestions for subjects to be dealt with in symposiums Those who have preferences as to the exact date are asked to communicate immediately with Dr Harald J C Okkels University of Copenhagen, secretary of the local committee —The seventh International Genetics Congress will be held in Moscow in 1937 definite dates are yet to be selected—The Sixth International Congress of Physical Medicine will meet in London, May 12-16 The congress has been divided into six sections kinesitherapy, physical education, hydrotherapy and climatotherapy electrotherapy, actinotherapy, radiotherapy and radium therapy Subjects for discussion are in three groups, according to an announcement physiologic and biologic study of physical agents, clinical indications for physical treatment and benefits and proper use of exercise in the healthy and a comparative inquiry into the teaching of physical medicine in different countries The secretary is Dr Albert Eidmow, 4 Upper Wimpole Street, London, W 1 —The one hundred and fourth annual meeting of the British Medical Association will be held at Oxford, July 17-24, under the presidency of Sir James W Barrett, Melbourne, Australia

Government Services

Announcement of Wellcome Prize for 1936

The Wellcome Prize will be awarded this year for the best paper on the subject "Importance of Coordinating the Military and Naval Medical Service with the Civilian Medical Profession" The prize is awarded by the Association of Military Surgeons of the United States

Dr DeWitt Appointed Assistant to Surgeon General

Col Wallace DeWitt has been appointed assistant to the surgeon general of the U S Army, Major Gen Charles R Reynolds, with the rank of brigadier general, succeeding Brig Gen Matthew Delaney, who retired November 30 Colonel DeWitt is 57 years of age and a graduate of the University of Pennsylvania School of Medicine, class of 1900 The following year he became an assistant surgeon in the U S Army, advancing through the grades until 1927, when he was promoted to colonel in the regular army He has been stationed at various posts through the United States and the Philippine Islands in various capacities, while his recent years have been spent as commanding officer of the Station Hospital, Fort Sam Houston, from 1921 to 1927, and of the Letterman General Hospital 1927-1931 When relieved of this duty he became professor of military hygiene and post surgeon at the U S Military Academy, West Point, N Y He was assigned to the Army Medical Center in Washington, July 9, 1935

Tuberculosis in Government Dairy Herd

An outbreak of tuberculosis in a herd of dairy cattle at the federal experiment station at Beltsville Md is reported by the Department of Agriculture Eighty-two reactors to the tuberculin test and eleven 'suspects' were revealed in a test made January 16 In the last previous test in October, one reactor appeared In accordance with the policy of the department the affected animals are being slaughtered and subjected to postmortem examination Officials were at a loss to explain

the sudden and extensive outbreak, a study is now being made to determine whether a virulent strain of the bovine organism gained access to feed or water The herd has been in an accredited status for eighteen years and has been maintained almost entirely by replacements raised on the farm No danger to other herds is involved, the department announced since all cattle that have outlived their usefulness for experimentation are slaughtered None are disposed of for dairy or breeding purposes

Annual Report of Veterans' Administration

During the fiscal year ended June 30, 1935, the Veterans' Administration hospitalized 153,018 patients, of whom 42,984 remained in hospitals at the end of the year, an increase of 7 per cent over the previous year Of the number still hospitalized, 55 per cent were being treated for neuropsychiatric diseases 12 per cent for tuberculosis and 33 per cent for general medical and surgical conditions There were 106,897 admissions, about 88 per cent of which were for non-service-connected disabilities This number is an increase of 67 per cent over 1934 but is 28 per cent less than the peak of 148,662 in 1932 Of the admissions, 10,387 were for observation or treatment of tuberculosis, 7,539 for psychotic or mental diseases, 9,680 for other neurologic disorders and 79,291 for general medical and surgical conditions

Deaths in hospitals totaled 7,253, or 7 per cent of the discharges, which amounted to 102,473 The previous year there were 5,334, which were 9 per cent of the discharges Of the deaths, 4,340, or 59.84 per cent occurred among patients under treatment for general diseases 1,885, or 25.57 per cent, for pulmonary tuberculosis, and 1,058, or 14.59 per cent, for neuro-psychiatric diseases

Since March 1919, when hospital facilities were first authorized for veterans of the World War, there have been 1,448,421 admissions to hospitals, the administration reported Since June 1924, when hospitalization was first authorized for all veterans without regard to the origin of their disabilities, 677,394, or 66 per cent of all admissions, have been for disabilities not connected with the service

The administration reported 9,323 veterans under domiciliary care June 30, 1935, of this number 80 per cent were veterans of the World War with an average age of 43 During the year there were 8,656 admissions for domiciliary care 85 per cent of them for non-service connected disabilities From these facilities 10,612 veterans were discharged after an average of six and a half months of domiciliary care

At the end of the year under report the Veterans' Administration was operating hospital facilities at eighty locations in forty-three states, with a total of 44,793 beds, there were 20,073 beds available for domiciliary care, a decrease of 3,474 from the number of the previous year Since the end of the fiscal year, Congress has appropriated \$21,250,000 for 12,116 more beds to be available within three years This addition will make a total of 55,858 beds in government facilities for hospitalization of veterans, not including 21,216 for domiciliary care In addition, the administrator of veterans affairs was authorized to submit estimates for the following new construction 500 bed neuropsychiatric hospital in Tennessee or Alabama 350 bed general hospital in or near Detroit, 100 bed general hospital near White River Junction, Vt, and a treatment station of twenty-five beds with space for a regional office at Reno Nev

Actual net disbursements for all purposes for the activities under the jurisdiction of the administration amounted to \$618,522,341.50

The report lays emphasis on opportunities extended to the medical personnel for training and advancement in the specialties of medicine Graduate courses have been provided since 1928 at the facility at Washington, D C, and until recently at Palo Alto, Calif In addition graduate study at civilian medical centers has been authorized, 455 physicians having had the benefit of this study Special courses in pathology, roentgenology, operative surgery, urology, electrocardiography and other subjects have been given at the facilities During the fiscal year 1935 an allergy clinic was established at Aspinwall Pa, which provides instruction for physicians and a laboratory for the preparation of allergens At Hines Ill a cancer service of 255 beds is maintained with equipment for research and treatment including 3 Gm of radium and two high voltage x-ray machines Five auxiliary cancer clinics have been established to take care of the increased cancer load among veterans At Dayton, Ohio, research is being conducted in the use of artificial fever in the management of arthritis, dementia paralytica and other forms of neurosyphilis

The Medical Profession and Voluntary Euthanasia

The movement of the Voluntary Euthanasia Legalization Society to make legal the terminating of painful incurable disease by the physician at the request of the patient has received influential support from both the profession and the public, but it has also excited much opposition. The medical journals have devoted editorials to the subject but they have refrained from committing themselves to support or opposition. The medical profession has begun to react to the proposal in the correspondence columns and so far there is more opposition than support. In the *British Medical Journal* Dr R. A. Fleming, consulting physician to the Royal Infirmary and physician to the Royal Hospital for Incurables, Edinburgh, describes the lives of cancer patients in the hospital as by no means dull, valueless or so miserable that they would welcome release. He always taught his students that pain should be soothed by drugs. To this communication Dr Killick Millard, founder of the movement, replies that voluntary euthanasia is not intended for the many patients with incurable disease who do not suffer pain and are happy and cheerful, but only for the comparatively few who are distressing, though in the aggregate the number is considerable and quite sufficient to justify the proposed legislation.

In the *Lancet* two surgeons take a different line, pointing out the value of surgical alternatives to euthanasia. Mr A. S. Blundell Bankart, an orthopedic surgeon asks whether the members of the society are aware that no patient need suffer intolerable pain from any local disease situated below the segmental level at which bilateral chordotomy can be done—the fifth cervical segment of the spinal cord. It is true that the operation might prove fatal, but that should meet with the approval of the society. However, the operation is not particularly difficult or dangerous, and Mr Bankart has never known of a death directly due to it. He does not put this suggestion forward as an argument against the aims of the society but thinks that it limits considerably the field of its concern. Those who are especially concerned with the treatment of such conditions as inoperable cancer of the pelvic organs might give consideration to the surgical relief of pain. Mr Lambert Rogers, professor of surgery in the University of Wales supports Mr Bankart's suggestion. He states that even before the failure of drugs to relieve pain, surgical relief is frequently advisable in order to prevent the demoralizing effect of large doses of opiates. He has found bilateral division of the pain tracts in the cord valuable in relieving the pain of advanced malignant disease. The outlook for the patient may thus be brightened and entirely changed. In reply to this suggestion, the surgeon H. H. Greenwood, a member of the Consultative Council of the Voluntary Euthanasia Society points out that chordotomy has but limited scope. It is impracticable in cancer of the tongue, pharynx, thyroid, larynx and esophagus. He refers to the widespread belief that lingering cases of fatal disease are ministered to by trained and sympathetic nurses and by every resource of medical science. The hideous truth is that the majority of these patients are discharged from the hospital and terminate their pitiable existence in poor homes. Even in hospitals there is a residuum for whom alone the bill is designed relief of whose sufferings is beyond medical skill.

The Reform of the Medical Curriculum

As previous letters show, the reform of the medical curriculum has been under discussion for some time. The report of a committee of the General Medical Council (*THE JOURNAL* July 20, 1935, p. 210) was circulated to the licensing bodies

and the deans of the medical schools for their observations. As a result of the replies a revised report has now been submitted to the council, of which the following are the main points.

PREREGISTRATION EXAMINATIONS

Before beginning the medical curriculum proper an examination should be passed in general education, chemistry (theoretical and practical), the elementary principles of the chemical combination of elements, physics (theoretical and practical), the elementary mechanics of solids and fluids, the elements of heat, light, sound, electricity and magnetism, elements of general biology (including practical work), fundamental facts of vegetable and animal structure, life history and function and introductory embryology. The examination in biology may be taken after registration in the period of professional scientific subjects.

THE MEDICAL CURRICULUM

The period of study from registration to diploma should not be less than five years. The first two years should be devoted to professional scientific subjects with an introduction to clinical subjects. Throughout the whole period of study, attention should be directed to the measures by which health may be assessed and maintained and to the prevention of disease. The professional scientific subjects include dissection of the entire cadaver, anatomy of the living body, embryology, histology, the elements of genetics, general physiology, the normal reactions of the body to injury and infection (as an introduction to general pathology and bacteriology), and the elements of normal psychology. In the second year, instruction should be given in the methods of clinical examination, including physical signs, the stethoscope and the ophthalmoscope, the examination of body fluids and introductory pharmacology.

THE PERIOD OF CLINICAL STUDIES

The period of clinical studies occupies the third to the fifth years, during which clinical instruction should be continuous. Students should not pass to this period until they have passed the examinations of the first and second years. A minimum of three years should be given to clinical study in an approved hospital. The medical training includes a clinical clerkship for six months, a continuous period of not less than a month's residence in a hospital or nearby, a clinical clerkship of not less than one month in a children's ward or hospital, regular attendance in an outpatient department for three months, regular instruction and demonstrations in applied anatomy and physiology by the teachers of those subjects as well as those of clinical subjects, instruction in therapeutics (including dietetics, prescribing, physical therapy and nursing) children's diseases and welfare, acute infections, tuberculosis, psychology, mental diseases and deficiency, dermatology, radiology and vaccination. The surgical training includes a surgical internship for six months, during which time the student should spend the greater part of his time at the bedside and in the outpatient department, a continuous period of not less than one month's residence in a hospital, regular attendance in an outpatient department for three months, surgical methods including physical therapy, minor operative surgery on the living, administration of anesthetics (not less than ten times), a course of operative surgery, regular instruction and demonstrations in applied anatomy and physiology by the teachers of these subjects and those of clinical subjects, disease in infancy and childhood, ophthalmology including refraction, otology, rhinology and laryngology, surgical radiology, venereal diseases, orthopedics, and dental diseases. The training in midwifery, gynecology and infant hygiene includes systematic instruction, the applied anatomy and physiology of pregnancy and labor, clinical midwifery, maternity and gynecologic practice for six months not less than two months' residence in a maternity hospital during which the student should attend at least twenty cases under supervision, antepartum and postpartum care, and management of the puerperium.

and new-born infant. Pathologic and bacteriological instruction includes general and special pathology (functional and structural) morbid anatomy, clinical and chemical pathology, general and clinical bacteriology, and immunology. Other subjects of instruction are pharmacology, materia medica (including practical pharmacy), hygiene and public health, forensic medicine, and the legal and ethical obligations of physicians, including national health insurance and other acts of parliament. It will be noticed how exceedingly practical is the curriculum, of which many of the requirements are new.

Reduction of Road Accidents

Official figures just issued show a reduction in the terrible toll of road accidents. During 1935 there were 822 fewer deaths and 12,802 fewer injuries than in 1934. The following table gives the comparative figures:

	1934	1935	Reduction
Killed	7,343	6,521	822
Daily average	20	18	2
Injured	231,603	218,798	12,805
Daily average	634	599	35

The reduction is stated by the minister of transport to be due to the safety measures he has introduced such as pedestrian crossings and the 30 miles an hour speed limit in built-up areas. It is noteworthy that the killed have been reduced in about twice the proportion that the injured have. This is explained by the reduction of speed rendering accidents less fatal. In London, during 1935, 1,116 persons were killed and 55,517 injured. The corresponding figures in 1934 were 1,448 and 59,510. Thus there was a reduction of 332 killed and 3,993 injured. In a broadcast speech the minister of transport said that, although there has been an average addition of 480 automobiles every day throughout the year, the number of persons killed or injured on the roads had fallen from 99 for every 1,000 vehicles in 1934 to 87 in 1935. Figures for London showed an alarming increase in the casualties to bicyclists, whereas injuries to pedestrians and other road users had been reduced. He reminded bicyclists of the provisions in the highway code to ride not more than two abreast and, where conditions warranted, in single file, also not to cut in or out.

PARIS

Jan. 3, 1936

Occupational Diseases

The law making obligatory the declaration of occupational diseases dates from 1919. But it applied only to certain of the most important ailments. A decree of Oct. 15, 1935 increased the number of those diseases, and they are numerous. Here is the list: first every disease caused by lead, its alloys and combinations, mercury, arsenic, phosphorus, nickel, fluorine and allied substances, carbon sulfide, chromic acid and chromates, manganese dioxide and pyrolusite, zinc, halogenic derivatives of the carbohydrates of the greasy order (*serie grasse*), benzene and homologous liquids, trinitrophenol, chloroform, and the like, irritant gas and vapors of any kind, cellulose paints and varnishes, alkali and caustic bases, tar, pitch, mineral oils, opium, emetine and quinine alkaloids. To the list are added physical agents such as short wave radiations, radium, and sudden variations of pressure, some irritant foreign timber, and biologic agents, such as bacteria and *Ancylostoma*. The enumeration covers also any product responsible for dermatoses, the powders, either siliceous or ferric, and the dust of wool, every repeated trauma causing inflammation of serous bursae or ligaments or of chronic arthritis, every repeated noise that might cause deafness, and every cause of conjunctivitis or even *in stagmus*.

The difference between the former law for the protection of workers against occupational hazards is that the law formerly

related only to emergencies the cause of which was sudden and unexpected, whereas the worker is now guaranteed against every risk that can be traced to his occupation. He is now entitled to receive half his salary, and a pension if partial or total disability occurs, his family is indemnified in case of death, and he can be treated free by the doctor of his choice, who is paid by the employer. The only great risk of disease not covered by the law is tuberculosis, unless it is the consequence of some traumatism or former contamination. But in this case the worker is protected by the *Assurances sociales* which pay during three years the expenses of sanatorium or special surgery and aid the family. Apropos of tuberculosis another recent decree includes the suppression of the 100 per cent bonus to the pensioned for tuberculosis who would refuse to entrust their children to the care of special organizations. Too often, as a matter of fact, they kept with them their babies, disregarding the risks of contamination. On the other hand, the pensioned for tuberculosis are now bound to give evidence, every three months that they have received regular treatment.

The Vernes Resorcinol Reaction for Tuberculosis

Years ago, Vernes proposed, for the diagnosis of latent tuberculosis, a flocculation test of the blood based on the principle that a suspension of resorcinol causes flocculation of all serums but most of all the serum of the tuberculous. The extent of this flocculation can be read with a photometer and is called the optic index. An optic index greater than 30 shows tuberculosis. Andre Richard Mozer and Mlle Madeleine Poidevin have tried this reaction in osteo-articular tuberculosis in 120 children, in the Maritime Hospital in Berck. The children were from 4 to 15 years old and were selected at random from more than a thousand other tuberculous children. These workers conclude that for diagnosis the Vernes reaction is of little value. When positive, it is an important sign of tuberculosis, but it lacks responsiveness and is negative in 75 per cent of the active cases. In prognosis it seems to have no practical value.

The Hippocratic Oath

France does not like ceremonies, even if they include in the ethics of some profession an element of history, tradition and cooperation. The oath of Hippocrates, for instance, which was in former times a solemn and sacred introduction to medical life, was suppressed after the French Revolution in many of the French faculties although maintained in some others. In the Faculty of Marseilles, which is one of the oldest of the French universities, having succeeded the ancient faculty of Aix, the candidate after the discussion of his thesis, and facing the assembled body of professors, stands up and, with right hand raised, utters the oath of Hippocrates. This custom has just been restored in the University of Paris and this restoration, initiated by Dean Roussy, must be considered one of the many measures demanded by the best part of the profession in order to maintain a high standard of morality among the body of physicians young and old.

Spirochetal Epidemic Meningitis in Children

Drs. Julien Marie and Pierre Gabriel had the opportunity last summer to observe some cases of acute meningitis. Three cases were treated in their hospital. Three children, between 10 and 13 years of age swam in the same river near Paris. Inquiry revealed that other boys who swam in the same river presented the same symptoms called acute meningitis by the local practitioners. In the three former boys evidence of the spirochetal nature of the meningitis was given by a high rate of agglutination and by the inoculation of guinea pigs. The onset was sudden with an unquestionable syndrome of meningitis, the fever reached 40 C (104 F) and lasted six or seven days. The spinal fluid presented a high cytologic reaction, reaching 450 leukocytes, which disappeared slowly about the

twentieth day. It was sometimes a lymphocytosis, sometimes polynucleosis. The termination was regularly in the direction of recovery, without any sequelae. Those cases are probably the first ones of epidemicity of the meningitic form of spirochetosis. The authors think that the epidemic conditions are most probably associated with swimming in a contaminated river, but one must consider also that the houses of the patients were infested with rats. The site of entry was perhaps the conjunctiva. These cases occurred in the summer months. The fact that the exact nature of the disease was ascertained only by biologic research indicates that many similar cases are perhaps undiagnosed and called simply meningitis by poorly equipped country practitioners.

Dec 23 1935

The New State Physicians' Law

The German government published the long awaited and much advertised state physicians' ordinance, Dec 13 1935, which will go into effect April 1. It is comprehensive legislation relating to the medical profession and represents years of careful preparation. While retaining what is worth while in previous legislation, it adds much that is new and in keeping with the present day concept of the state. The ordinance originated in the need for a comprehensive regulation of the licensing and practice of the medical profession throughout the reich. Previous legislation governing the profession in the respective states as well as courts of professional honor is abolished and superseded by the new national legislation. In general the new membership of the medical profession will be placed under the supervision of the minister of the interior. The regulatory powers of the minister of labor which apply to medical service in the social insurance societies, sick benefit societies and so on, will remain undisturbed. The *Kassenarztsche Vereinigung Deutschlands* (insurance physicians union of Germany) founded in 1933 also remains although it now becomes an adjunct of the *reichsarztekammer* (state physicians' chamber) and legal successor of two hitherto existing organizations the *'Deutsche Aerzterebund'* (German physicians' association) and the *"Verband der Aerzte Deutschlands"* (league of physicians of Germany) or Hartmann league, which according to the new law, will be disbanded.

The *reichsarzteordnung* contains ninety-three paragraphs arranged in five sections. The principal four sections deal with (1) the physician (2) the German medical profession (3) penalties for professional offenses and (4) government supervision. The following quotation from section 1 shows clearly the importance of this comprehensive legislation. 'The physician is called on to administer to the health of the individual human being and to that of the people as a whole. He fulfils the latter function through public duties as regulated by this statute. The medical profession is no trade.'

The first section goes on to outline in eighteen paragraphs the concept of the medical profession and to deal with the appointment of physicians a term which replaces the certification heretofore in use. Accordingly only the person officially authorized or 'appointed' will be allowed to practice medicine and to designate himself 'physician'. The appointment is valid for the entire reich. Only a physician duly appointed in such a manner may be called on to fill any post involving medical practice or science within the gift of any authoritative or legislative corporate body. This does not apply to persons who are employed under the direction or supervision of a physician. Appointment is made by the minister of the interior on recommendation of the *reichsarztekammer* to such persons as fulfill the requirements of the laws governing appointments. Appointment will be denied or revoked (1) when the applicant does not possess civil rights (2) when he is lacking in national and

moral reliability, particularly if he is alleged to possess criminal or vicious traits, (3) when the applicant is declared professionally unqualified, (4) when the applicant is deemed unsuitable or unreliable because of a physical deformity or some mental deficiency or because of a disease, (5) when the applicant is ineligible for government service by reason of his racial extraction or that of his wife and when, at the time of application, the proportion of physicians of other than German extraction to the total number of physicians in the German reich exceeds the proportion of non-German inhabitants to the total population of the reich. The provisions of the existing statutes governing officials heretofore were applied primarily to the *kassenarzte* (sick insurance physicians), besides, following a regulation of the minister of education, physicians' licenses have been refused non-Aryan candidates on general principles. According to the new legislation appointment of non-Aryans shall henceforth be determined by the proportionate number of non-Aryans within the population as a whole, that is to say, about 1 per cent (here as in the laws governing officials, one non-Aryan grandparent or marriage with a non-Aryan constitutes sufficient ground for a refusal). Thus henceforth a numerous *clausus* will apply to non-Aryan physicians not only in the *kassenpraxis* (insurance practice) but in general practice as well. This will scarcely have any important results for the time being as the proportion of non-Aryan physicians still exceeds the legal maximum. By reason of physical defects and so on (item 4) the authorization to engage in the practice of medicine can be revoked as the occasion warrants. Revocation can be made also in case of a duplication of professional income (as for example in the case of a woman physician whose husband follows the medical profession and derives an income from it). Resignation of an appointment is permissible. It is illegal, however, to practice medicine either professionally or factually if the appointment has been revoked or renounced or if application for an appointment has previously been denied. A physician is forbidden also to change his status to that of a *heilkundiger* (lay practitioner), as occasionally has been done in an attempt to make larger profits. It is expressly stated that 'the physician is duty bound to exercise his profession conscientiously and to show by his conduct within and without the sphere of his professional activities that he is worthy of a respect and confidence compatible with the high standards of his calling.'

Regulations concerning professional duties and questions of professional ethics are further provided for in a *Berufsordnung* (professional ordinance). It represents a heretofore unheard of extension of governmental authority into medical activities.

Maximum physicians' fees as fixed by the fee ordinance can be exceeded only with the approval of the *reichsarztekammer* in the absence of a written agreement.

Any person who, lacking an official appointment as physician, styles himself by a designation resembling that of a physician and which conveys the impression that such person has been duly authorized to practice medicine under the official designation of 'physician,' shall be subject to imprisonment for a term not to exceed one year or a fine or to both penalties.

Special attention is called to the stipulation that physicians, in the exercise of their profession, are forbidden the use (on announcements, name plates and prescriptions, for example) of any designation that refers to the activities of some predecessor.

The second section, of thirty-two paragraphs, is dedicated to the *reichsarztekammer*. It states that 'the vocation of the German medical profession is to effect in the interest of the welfare of people and reich the preservation and improvement of the health of the good heredity and of the racial stock of the German people.'

In future the membership of the German medical profession will present three gradations: first each physician must belong

to a *bezirksvereinigung* (district organization), above these local groups will be a "regionale aerztekammer" (regional chamber of physicians), while supreme medical authority will be vested in the *reichsarztekammer*, whose director (*reichsarztfuhrer*, *reich physician leader*) shall be appointed or removed by the fuhrer and chancellor of the reich on recommendation of the minister of the interior acting in conjunction with the leader of the National Socialist party. The rights of the district organizations over their own membership shall be restricted. For members of the *reichsarztekammer* and the regional chambers as well as for the district leaders the provisions of the "statutes governing officials" apply with special regard to the antecedents of the physician and his wife. In these capacities physicians having one Jewish grandparent or a non-Aryan spouse will not be permitted to serve. Exceptions may be allowed by the director of the *reichsarztekammer*.

The director of the *reichsarztekammer* is assisted by a permanent vice director. The director is empowered also to deputize others for the performance of various duties. An honorary board of which the membership is of his own choosing serves the director in an advisory capacity. This board consists of members of the *reichsarztekammer*, the director of the *kassenarztliche vereinigung* a representative of the regional chambers, and at least one government physician.

Membership in the subordinate organizations is regulated along similar lines. Members of the regional chambers (excepting the adviser who is honorary) are always representatives of the district organizations and the medical faculty of the district as well as being official physicians.

Membership in each *aerztekammer* is for a period of four years. The election of the majority of the members takes place as follows: from five names submitted to it the *reichsarztekammer* selects and appoints two physicians: a regular representative and a substitute.

It is important to note that the directors of the *reichsarztekammer* and the regional chambers as well as the directors of the district groups are not bound to agree with the stands taken on a subject by these respective bodies. They must state the reasons for their opposition, however for purposes of record.

All physicians in the German reich including research workers and university professors are controlled by the *reichsarztekammer*. The only exceptions are medical officers of the army and navy on active service. Regulations of the *reichsarztekammer* are binding except that they must not interfere with the service activities of medical officials. The *reichsarztekammer* can exact fines up to 1,000 reichsmarks for violation of rules. Every physician residing in a given district belongs to the district organization and a newcomer must announce his presence to the organization. The regional chamber controls all physicians belonging to the district organizations within its sphere. The *reichsarztekammer* shall maintain an official register of all physicians in the reich. All physicians pay compulsory dues to the *reichsarztekammer*.

It shall be the duty of the *reichsarztekammer* to uphold superior scientific and ethical medical standards to see to it that professional honor is maintained and professional duties fulfilled and to foster the education and training of physicians by the creation of facilities necessary thereto. It shall further be the duty of the chamber to promote cordial relations between physicians and to effect an equitable distribution of physicians throughout the reich for the benefit of the profession and of the population as a whole. This means that no establishment of a physician in a certain locality can take place without the consent of the chamber. Moreover, it engages in benevolent activities such as the creation of insurance for the protection of physicians and their dependents in times of emergency.

In addition, the *reichsarztekammer* is empowered to issue special regulations which will assure participation of the physician in the duty of preserving and improving the heredity and the racial stock of the German people, likewise in collaboration with the state bureau of health and the bureau of statistics it may exercise supervision or issue instructions with regard to questions of health, heredity and race. The *reichsarztekammer* has the further authority to assist the public as well as the party in all matters relative to the medical profession especially by furnishing expert opinion and advice.

Medical treatment is considered a part of public welfare service with the exception of such institutional treatment as is reserved for free professional medical activity. Only the *reichsarztekammer* can conclude agreements with the public welfare agents concerning the activities of physicians, it alone determines the conditions under which physicians are permitted to give treatment; it dictates the terms of the agreement and issues regulations for the physician. It makes special binding rules concerning the economic wisdom of therapeutic measures and prescriptions. Medical treatment in the public health service by an individual physician can also be subject to regulation by the *reichsarztekammer*.

Permanent arbitration committees will be established within the district organizations to deal with differences between physicians. In case of a withholding of information or a refusal to appear in person before the committee, a fine not to exceed 1,000 reichsmarks may be imposed as penalty. Should the arbitration committee fail to bring about an agreement, the director of the district organization makes an arbitration if the persons concerned so wish and thus further legal procedure is out of the question.

The third section, of twenty-seven paragraphs stipulates the punishment of professional offenses; it is intended for the physician who is lax in the performance of his professional duties. Violations of the professional ordinances especially are involved. The penalties with which the guilty one is threatened are warning, censure, a fine not to exceed 10,000 reichsmarks, suspension from public welfare activity for a definite or indefinite period of time and finally declaration of the guilty person to be unfit to practice the medical profession. In particular cases the penalty may be made public. Warning, censure, a fine not to exceed 1,000 reichsmarks and suspension from practice can be imposed by the *reichsarztekammer* without further legal proceedings. The more severe penalties however can be inflicted only by the professional medical court. The procedure to be followed in various cases is precisely outlined. Among others after a criminal procedure has resulted in acquittal a professional procedure can be instituted only if the offenses, while not constituting a breach of the criminal law, violate the professional regulations.

Professional legal procedure may be instituted on the motion of the board of control or of the *reichsarztekammer*, proceedings may also be brought against a physician at his own request if he wishes to clear himself of suspicion. The district professional tribunal consists of a president with judicial powers and two other physicians; the medical law court or professional court of first instance for the entire reich consists of a president with judicial powers and three physicians. The members of these tribunals should not at the same time be executive officers of the *reichsarztekammer* or of the subordinate organizations. The procedure before the professional tribunals is based on existing civil service procedure against accused government officials. A prosecutor is not provided for. The accused may be defended by an attorney, another physician or any authorized official. The president can, without further proceeding bring the trial to an abrupt close if the penalty of a warning, a censure or a fine not exceeding 500 reichsmarks is deemed sufficient. Against such a closing of the case, how

ever, all who wish may voice their opposition. From a decision of the medical district court, the board of control or the *reichsarztekammer*, the convicted physician may lodge an appeal with the physicians' supreme court. The decision of this court is final. It is in no way bound by the finding of the district court. It can even change the *res gestae* or remand the case to the lower courts.

When a legal professional action is taken against a physician that is likely to result in his being declared unfit to practice medicine, a preliminary suspension from professional activity can be ordered by the district court. Moreover, such suspension may be imposed, after a hearing before the *reichsarztekammer*, on any physician imminently suspected of serious dereliction in his professional duties. On the other hand, if an action based on gross carelessly reported information is instituted, the costs will be assessed against the person making the allegation.

Among further stipulations worthy of mention is the regulation that authorizes the *reichsarztekammer* to disband any physicians' organizations having as their function the observation of professional economic interests or other affairs. The minister of the interior can likewise in collaboration with the minister of education and after a hearing by the *reichsarztekammer*, disband any organization interested in the advancement of medical science. For the establishment of new organizations of this type, permission of the minister of the interior is required.

Unquestionably, the legislation here broadly summarized, based on long standing knowledge of conditions, and clearing up as it does so many points, is a progressive step in the right direction.

Whether or not these innovations will stand the test of time remains for the future to say. It is a source of gratification that at last, for once, the German physicians are distinctly removed from the status of tradespeople in which a tax-inflicting bureaucracy had placed them—a situation which militated against both their self respect and their professional class consciousness. The reich physicians' ordinance places the professional life of the physician on a new plane. For the first time he is united with his colleagues throughout the reich and the fundamentally independent character of the profession is upheld.

The Tercentenary of the University of Budapest

From October 23 to 29, in the presence of distinguished scientists of the world, a celebration was held of the three hundredth anniversary of the university founded by "Cardinal Cicco," Peter Pazmany, the Budapest University of today. At first and during the Middle Ages it had only theological and philosophical faculties, to which the successors of Peter Pazmany, in the primate's seat, Losy and Lippay, added in 1667 the legal faculty, filling four chairs with Jesuits. The faculty of medicine was founded through the benevolence of Queen Maria Theresa in 1777, in which year the university moved from Nagyszombat to Buda, the ancient part of Budapest, and in 1784 to Pest. Up to 1848 the university was conducted by the Jesuit order and later by the royal vicerent council. An act of parliament in 1848 proclaimed the freedom of teaching and learning and placed the university wholly under the control of the Hungarian government.

The jubilee was celebrated with splendor enhanced by the presence of delegates from 130 foreign universities. The celebration was opened by Regent Horthy and Dr. Korniss, rector of the university who in his opening address emphasized that the university was founded in the most tragic epoch of the nation. He pointed out that Hungary stopped the influx of

Tatars and Turks, and that if the Magyars had not fought this battle the Koran would be taught today in Oxford and Cambridge. Former rector Balazs Kenyeres spoke about those modern students who brought fame to Budapest University by their work done abroad. Their thirst for science drove Hungarian students in swarms to Germany, Italy, England, France, Norway, Netherlands and other centers, where many of them gained fame. The Vienna, Cracow, Prague, Konigsberg, Wittenberg and Leipzig universities had Hungarian rectors. A Hungarian, Mihaly Kassai, founded one of the famous libraries of the university of Wittenberg. Another Hungarian, Uri Janos, became the librarian of the university of Oxford. On the recommendation of Boerhaave, the Dutch professor, Paul Gyongyossy became the house physician of the Tsarina Elisabeth. Balsarati was appointed court physician to Pope Paul V, another graduate of Budapest University. Michael Zichy, became the court painter of the Russian tsar. Many Hungarians became explorers and discoverers. Count Moritz Benyowszky became king of Madagascar. Korosi Csoma Sandor edited the first dictionary of the Tibetan language. Gheorghe Almassy made explorations in China, Count Eugen Zichy in the Caucasus, and Samuel Fenichel and Louis Biro in New Guinea. Anyos Jedlig constructed in 1827 the first electric motor and in 1859 the first electric dynamo. Farkas Kempelen (1734-1804) constructed a writing and talking machine and also a chess automaton, which may be seen today at King's College, London. Professors Dery and Zipernowsky invented the electrical transformer, Donath Brink, the carburetor. The first underground electric railway was built by Hungarian engineers in Budapest and was opened in 1895.

Three Nobel prize winners are of Hungarian origin, Philip Lenart, Barany and Zsigmondy. Janos Raymann of Eperjes experimented with cow vaccination in 1717, four years prior to the English Jenner, and Stephan Veszpremy, a practitioner of Debretzin, worked in London on therapeutic inoculations against disease. His priority on this field of medicine has been acknowledged. Hodossy Szolanits Ferencz experimented in 1773 with inoculating insane patients with pus, with the intention of producing a curative fever. The first publication in medical literature of purely laryngologic nature was from the pen of Csermak, professor at Budapest University, in the *Orvosi hetilap*, which is today the leading Hungarian medical journal. Ignatz Semmelweis was a Hungarian physician who constantly accentuated his Magyar origin by wearing the Magyar costume, the braided mantle. His discovery of the cause of puerperal fever was extremely important to mankind.

A special ophthalmologic chair was created in Budapest in 1804, and in 1874 dermatology was accorded a special chair. With slow progress, Budapest University came to be the most frequented university of the world. With its ever increasing popularity and the strong feeling of the Magyars for scientific learning came the endeavor to improve high schools. In 1872 Kolozsvar University was founded in 1912 Pozsony University and in 1914 Debretzin University.

Professor Kenyeres continued his address with a pathetic reference to the cruelty of fate whereby Hungary has been deprived of two thirds of its territory. The misfortune of the war is felt also by our ancient university which lost its mighty estates to Czechoslovakia and which has received them back just now, thanks to the wise decision of the Hague international court. The old link with foreign scientific institutions is limited by the economic position of the state, and the number of university chairs has decreased from 113 to 97 and the number of the auxiliary staff from 367 to 265. Likewise the number of foreign books and periodicals had to be reduced. The position of Magyar youth became serious. The gates of the university had to be closed to many. Among such hardships

with superhuman effort only was it possible to help mothers, infants and children. In this field the National Public Hygiene Institute, founded and maintained by the Rockefeller Foundation, aids immensely.

On the occasion of the three hundredth anniversary of the founding of the university, the state donated a modern astronomical observatory and a seismograph. The faculty of medicine received a new clinic for tuberculous patients, and the state erected a huge home for indigent students.

In connection with the jubilee there was an exhibition of historical relics, including the foundation letter written by the great founder Peter Pazmany, the corroborating document signed by King Ferdinand II in 1635, and a document, called Diploma Inaugurale, written by Queen Maria Theresa enacting the reorganization of the university and the original matriculation books from 1635 on. The history of Budapest University will be shortly published in book form, comprising five volumes written by the present professors and late students of the university.

Medical Problems in India

Speaking to the Medical Missionary Association meeting in Melbourne, Dr H. Thomas of Madras, Southern India, described the appalling need for extension of medical service in India. It was difficult to know whether preventive or curative medicine was the more urgent, but curative treatment paved the way toward gaining the confidence of the villagers. In India 8,500,000 persons were born and 6,500,000 died every year. The present rate of increase was therefore 2,000,000 a year and if the fearful infant mortality should be reduced it would be necessary to provide employment and an object in life for a still greater population. That problem would be faced as soon as preventive medicine became more efficient. Despite the country's enormous wealth there was fearful poverty in India, and the per capita wealth was only £19 compared with £450 in England. Only 13.9 per cent of the Indian male and 2 per cent of the female population were literate. The problem of medical work was increased by the fact that 300,000,000 of the 350,000,000 population lived in villages. Centrally placed hospitals were usually established as transport facilities were good and leper and tuberculosis clinics and dispensaries had been established in surrounding villages. More than 50 per cent of the hospitals were self supporting. Dealing with the problem of child marriage, it was necessary to study customs and proceed by gradual evolution rather than by drastic change. The early maturity of Indians was one of the reasons for child marriage. It was hard to make the people understand that their early maturity did not mean marriage. They should be taught a moral sense, and a great service would be done by showing them that there was something beyond satisfaction of passion. Many missionaries felt the strain of the tropics and time and again the medical men had to deal with cases of men and women missionaries with a psychologic imbalance. This caused expense to the mission board and disappointment to the worker and indicated that a psychologic examination was as essential as a medical examination for intending missionaries. There was a tremendous lack of proper equipment and staff in Indian hospitals, and in the 253 mission hospitals and 6,000 government hospitals there were only 73,000 beds or one bed for each 5,000 of the population.

Medicine Through the Ages

The Public Library of Victoria, in conjunction with the British Medical Association, is holding in Melbourne an exhibition of rare medical books extending from 1700 B. C. to the present day.

Ancient medicine is represented by a facsimile of the Edwin Smith surgical papyrus, a manuscript written in Assyria in cuneiform characters, as well as the Ebers medical papyrus written in Egypt about 1500 B. C.

Hebrew medical hygiene of 500 B. C. from the religious point of view is one of the main themes of the Book of Leviticus. This is represented in the collection by a copy of the extremely rare Coverdale and Tyndale English Bible, printed in Antwerp in 1537.

Greek and Roman medicine from 400 to 10 B. C. is covered by rare editions of the works of Hippocrates, Aristotle, Lucretius and Celsus. From the second century the works of Galen were for hundreds of years the supreme authority on medical subjects, a well used student's edition of 1548 is shown.

Arabian medicine is represented by a manuscript copy of the Koran and the works of Avicenna. Several of the big encyclopedic works of medieval writers are on view including those of Vincent of Beauvais and of Bartholomew the Englishman both in rare fifteenth century editions. For the qualifications of a "Doctor of Physike" reference may be made to the extraordinarily rare first edition of Chaucer, published in London in 1532.

Two epoch making works of 1543 are on view—both, however, in later editions—the *Astronomia* of Copernicus and the *Fabrica* of Vesalius, the founder of modern scientific anatomy. In 1600 appeared the first great scientific book published in England, the "De magnete" of William Gilbert, physician to Queen Elizabeth.

Rare books of the seventeenth century include Harvey's book on the movement of the heart and blood, Bacon's "Advancement of Learning" and the first edition of Galileo's "Dialogues," published in 1632 and suppressed by the Inquisition. Among other interesting books of the same century is one by John Hall the son-in-law of Shakespeare, describing how he cured his wife's ailments and the "Bills of Mortality," published in London during the great plague of 1665.

Marriages

LOUIS CARROLL SCHUSTER to Miss Verna Mae Dill both of New Orleans, in Baton Rouge, La. Nov. 20, 1935.

H. BROOKS SMITH, Bluffton, Ind. to Miss Claudia Purkhiser of Indianapolis in Fort Wayne, Dec. 31, 1935.

HENRY BERNARD SHOWALTER, Kenbridge, Va. to Miss Edna Elizabeth Kiely of Marion, Dec. 19, 1935.

ISRAEL O. SILVER, Seelton, Pa., to Miss Miriam Stotsky of Lancaster in Philadelphia, Nov. 24, 1935.

EDWIN J. G. VALENTINE JR., Jersey City, N. J. to Miss Virginia Moll of Woodbridge, recently.

STANLEY B. GORDIN, Alquina, Ind. to Miss Dorothy Estelle Kelsey of Oakland, Cal., Dec. 22, 1935.

RICHARD D. SIMONSON, Boise, Idaho to Miss Marguerite Anne Genten at Winona, Minn. Oct. 11, 1935.

JOSEPH W. MCHUGH JR. to Miss Catherine Stackhouse both of Johnstown, Pa., Nov. 30, 1935.

WILLIAM H. MCCARTY to Miss Sallie Cynthia Holmes both of Marion, Va., Nov. 26, 1935.

HUBERT GROS to Miss Jean Kramer, both of Delphi, Ind., in Franklin, Oct. 17, 1935.

ALBAN F. TESSIER to Miss Ruth L. Kowalke, both of Milwaukee, Nov. 15, 1935.

JOHN S. WOOLERY, Bedford, Ind., to Miss Kay Craig of Detroit, Dec. 28, 1935.

GEORGE WILLIAM FOX to Miss Elise Scott, both of Milwaukee, Dec. 21, 1935.

LEO F. SCANLAN to Miss Louise Crist, both of Philadelphia, Nov. 27, 1935.

MORTON VESCHI to Miss Dorothy Skolkin, both of New York, Oct. 12, 1935.

Deaths

Walter Nelson Thayer Jr, Albany, N Y, New York University Medical College, 1897, past president of the American Prison Association, member of the National Committee for Mental Hygiene and the American Association for the Study of Feeble-minded, assistant physician to the Clinton Prison Dannemora, 1904-1913, physician to the Eastern New York Reformatory Napanoch 1913-1920, and superintendent 1920-1921, superintendent of the Institution for Defective Delinquents, 1921-1929, superintendent of prisons State of Maryland, 1929-1930, commissioner of correction, State of New York, since 1930, formerly member of cabinets of Governor Roosevelt and Governor Lehman, aged 60, died, January 6 of pneumonia

Howell Terry Pershing @ Denver University of Pennsylvania Department of Medicine Philadelphia, 1883 chairman of the Section on Nervous and Mental Diseases of the American Medical Association, 1912-1913, associate professor of neurology and psychiatry, emeritus, University of Colorado School of Medicine, member of the American Neurological Association consultant neurologist to the Denver General Hospital and the Children's Hospital, author of 'The Diagnosis of Nervous and Mental Diseases' in 1901, aged 77, died Nov 29, 1935

David Aloysius Prendergast @ Cleveland, Western Reserve University Medical Department, Cleveland 1906 member of the American Academy of Ophthalmology and Oto Laryngology, fellow of the American College of Surgeons, visiting otolaryngologist to St John's Hospital consulting otolaryngologist to the Lakewood Hospital and consulting oculist to St Ann's Hospital aged 54, died, Dec 2, 1935, of broncho pneumonia

Maurice I Rosenthal @ Fort Wayne, Ind, Medical College of Ohio, Cincinnati 1890 member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons and the American Radium Society, fellow of the American College of Surgeons, served during the World War for many years on the staff of St Joseph's Hospital, aged 66, died Dec 24, 1935, of a self inflicted gunshot wound

Harry Bergman, Livingston, Texas Tulane University of Louisiana Medical Department, New Orleans, 1895, member of the State Medical Association of Texas formerly secretary of the Polk-San Jacinto Counties Medical Society member of the city council, aged 61, medical superintendent and owner of the hospital bearing his name, where he died, Nov 20 1935 of heart disease

Henry Gray Anderson @ Waterbury Conn, College of Physicians and Surgeons Medical Department of Columbia College New York, 1889, past president of the New Haven County Medical Society fellow of the American College of Surgeons served during the World War aged 70 on the staff of the Waterbury Hospital, where he died Dec 18, 1935, of septicemia

Edward J Ryan, St John N B College of Physicians and Surgeons, Baltimore 1908 formerly assistant in pathology University and Bellevue Hospital Medical College New York at one time on the staffs of the Bellevue and St Vincent's hospitals New York served during the World War commissioner of St John General Hospital aged 52 died Nov 26 1935

William Lewis Wallace @ Syracuse N Y Syracuse University School of Medicine, 1897 one of the founders president of the board of trustees on the surgical staff and lecturer of anatomy and physiology Crouse Irving Hospital formerly on the staffs of the University Hospital and the Hospital of the Good Shepherd, aged 73 died, Dec 25 1935 of erysipelas

John Coleman Everett, Nellysford Va (licensed in Virginia under the exemption law of 1885) member of the Medical Society of Virginia secretary of the county board of health at one time member of the state board of health aged 73 died Dec 4 1935, in the University of Virginia Hospital Charlottesville, of carcinoma of the colon and bronchopneumonia

Winfield Scott Devine @ Marshalltown Iowa State University of Iowa College of Medicine Iowa City 1887 past president of the Marshall County Medical Society, formerly medical superintendent of the Iowa Soldiers Home Hospital aged 81 died, Dec 11 1935 in the Evangelical Deaconess Home and Hospital of heart disease

Melville Freeman Johnston @ Richmond Ind Bellevue Hospital Medical College, New York 1886 past president of the Wayne County Medical Society formerly city and county health officer, for many years member of the school board on the staff of the Reid Memorial Hospital aged 77 died Dec 29 1935 of cerebral hemorrhage

Millard Hunter Fortney, Arcola Ill, Loyola University School of Medicine Chicago, 1919, member of the Illinois State Medical Society, mayor, served during the World War formerly school board trustee aged 47, died, Dec 1 1935 of septicemia, which developed from an injury received in a fall

William A Geohagan, Dayton, Ohio Pulte Medical College, Cincinnati, 1882, formerly professor of practice of medicine at his alma mater at one time on the staff of the Bethesda Hospital, Cincinnati, aged 76 died Dec 18, 1935, of cardiovascular renal disease

Harry Reasoner Geyer @ Zanesville, Ohio Medical College of Ohio, Cincinnati 1892 fellow of the American College of Surgeons, on the staffs of the Good Samaritan and Bethesda hospitals aged 68, died, Dec 6, 1935 of hemorrhage due to gastric ulcer

Philip Gath, Cincinnati, Medical College of Ohio Cincinnati 1893 formerly assistant superintendent and resident physician to the Cincinnati Tuberculosis Hospital aged 67 died, Nov 23, 1935, of coronary occlusion, arteriosclerosis and hypertension

Arthur Ogburn Spoon, Greensboro N C, University of Maryland School of Medicine, Baltimore, 1908 member of the Medical Society of the State of North Carolina, aged 54, died Dec 10 1935, in the Wesley Long Hospital, of influenza and pneumonia

Clarence A Flowers, Wendell N C, College of Physicians and Surgeons, Baltimore, 1905 member of the Medical Society of the State of North Carolina aged 54, died, Dec 4, 1935 in the Mary Elizabeth Hospital, Raleigh, of acute dilatation of the heart

Edward Houghton Green, Legion Texas Jefferson Medical College of Philadelphia 1894, served during the World War connected with the Veterans Administration Facility, aged 68 died suddenly, Dec 19, 1935 in Kerrville, of dilatation of the heart

Rollin Theodore Adams, Mantorville, Minn, University of Minnesota Medical School Minneapolis 1893, member of the Minnesota State Medical Association past president of the Dodge County Medical Society aged 71 died Dec 6 1935

Matthew Porter, Dayton, Ohio, Medical College of Ohio Cincinnati 1897, member of the Ohio State Medical Association aged 65, on the staff of the Miami Valley Hospital, where he died Nov 25, 1935 of carcinoma of the pancreas

Samuel Hoffman Sidlinger, Hutchinson Kan, University of Michigan Department of Medicine and Surgery Ann Arbor 1874, member of the Kansas Medical Society, aged 90 died Dec 28, 1935 of a fracture of the hip and arteriosclerosis

Olney Windsor Phelps, Warren Mass Dartmouth Medical School, Hanover, N H, 1878, an Affiliate Fellow of the American Medical Association formerly member of the board of health and school committee, aged 86, died Dec 2 1935

Lynn Carl Smith, Adin, Calif Hahnemann Medical College of the Pacific, San Francisco 1906 aged 63 died Nov 25 1935, in the Veterans Administration Facility West Los Angeles, of carcinoma of the prostate with metastasis to the brain

Arthur Ernest Smith, Harrison Neb University of Kansas School of Medicine, Kansas City 1907 member of the county board of health and insanity board, aged 62 died Nov 21 1935 in Lusk Wyo, of cardiovascular renal disease

Charles Norris Stephenson, Milton, Iowa, Keokuk Medical College College of Physicians and Surgeons 1907 member of the Iowa State Medical Society aged 50 died Dec 19 1935, as the result of a smut infection and pneumonia

Bernard Francis Dorgan @ New Haven Conn Yale University School of Medicine New Haven 1926 aged 34 on the staff of St Raphael Hospital, where he died Dec 5, 1935, of peritonitis appendicitis, nephritis and uremia

George Hermann Wright @ New Milford, Conn, College of Physicians and Surgeons Medical Department of Columbia College New York 1894 aged 67 died, Dec 11, 1935, of chronic myocarditis and acute nephritis

John Andrew Devine, Bancroft, Iowa State University of Iowa College of Medicine Iowa City 1908, member of the Iowa State Medical Society aged 55, died Dec 10, 1935, of pneumonia following the amputation of a leg

Ira Edwin Durant, San Antonio, Texas, University Medical College of Kansas City Mo, 1898, member of the State Medical Association of Texas, served during the World War aged 64 died Dec 17 1935 in a local hospital

Dennis Wilhoit, Bagdad, Ky., Hospital College of Medicine, Louisville, 1900, member of the Kentucky State Medical Association, aged 66, died, Dec 21, 1935, in the King's Daughters' Hospital, Shelbyville, of heart disease

P Norman Sutherland Ⓢ Angola, Ind. Detroit College of Medicine, 1896, past president of the Steuben County Medical Society, secretary of the city board of health, aged 65, died, Dec 28, 1935, of cerebral hemorrhage

Ira Everett Dyas Ⓢ Eastport, Maine, University of Cincinnati College of Medicine, 1912, past president of the Washington County Medical Society, formerly member of the school board, aged 67, died in November

Paul Raymond Siberts, Somerton, Ariz. Northwestern University Medical School, Chicago, 1903, member of the Arizona State Medical Association, aged 59, died, Nov 22, 1935, at National Military Home, Calif.

William Francis, South Charleston, Ohio, Starling Medical College, Columbus, 1897, formerly mayor of South Charleston, past president of the board of education, aged 67, died, Nov 29, 1935, of cerebral hemorrhage

Allen Gray Sampson Ⓢ Philadelphia, Medical-Chirurgical College of Philadelphia, 1901, aged 57, died Nov 22, 1935, in the Graduate Hospital, of heart disease, cirrhosis of the liver, uremia and diabetes mellitus

Albert Allen Sanford, Duran, N. M. Vanderbilt University School of Medicine, Nashville, Tenn., 1882, member of the New Mexico Medical Society, aged 78, died, Nov 12, 1935, at Los Angeles, of myocarditis

William John Robb, Denver, University of Colorado School of Medicine, Denver, 1913, member of the Colorado State Medical Society, aged 52, died Nov 22, 1935, in Gallup, N. M., of pulmonary tuberculosis

Carlton Lee Starkweather, Ocequan, Va. Georgetown University School of Medicine, Washington, D. C., 1898, member of the Medical Society of Virginia, aged 71, died Dec 11, 1935, of heart disease

Carlo Pascarelli Ⓢ Brooklyn, Regia Università di Napoli, Facoltà di Medicina e Chirurgia, Italy, 1920, served in the Italian Army during the World War, aged 40, died Nov 27, 1935, of heart disease

Edward Chisholm Cobb, Ruther Glen, Va. University College of Medicine, Richmond, 1899, member of the Medical Society of Virginia, aged 59, died suddenly Dec 14, 1935, of angina pectoris

Darling L. Peeples, Navasota, Texas, University of Georgia Medical Department, Augusta, 1885, veteran of the Spanish-American War, aged 72, died, Nov 28, 1935, of coronary occlusion

John Charles Bennett, Waterloo, Iowa, Rush Medical College, Chicago, 1932, member of the Iowa State Medical Society, aged 32, died, Dec 10, 1935, in the Presbyterian Hospital of pneumonia

Robert Stewart Dowd, Quyon, Que., Canada, Trinity Medical College, Toronto, Ont., 1895, L. R. C. P., Edinburgh, 1895, aged 67, died, Nov 1, 1935, in the Ottawa (Ont.) Civic Hospital

Frederick N. Garand, Toledo, Ohio, Kentucky School of Medicine, Louisville, 1891, formerly member of the city council, aged 71, died Dec 4, 1935, in St. Vincent's Hospital, of diabetes mellitus

Mark Barton Smith, Los Angeles, Rush Medical College, Chicago, 1883, aged 77, died, Dec 16, 1935, in the Cedars of Lebanon Hospital, of arteriosclerosis, chronic nephritis and uremia

Gowan Ferguson, Great Falls, Mont., University of Toronto (Ont.) Faculty of Medicine, 1888, member of the Medical Association of Montana, aged 69, died Dec 5, 1935, of heart disease

John William Giles Ⓢ Nyack, N. Y., Hahnemann Medical College and Hospital of Philadelphia, 1885, on the staff of the Nyack Hospital, aged 73, died Dec 17, 1935, of heart disease

John Alexander Neff, Victoria, B. C., Canada, Trinity Medical College, Toronto, Ont., Canada, 1888, formerly medical officer of health of Ingersoll, aged 76, died Sept 10, 1935

Felix John Scheffler, Onawa, Iowa, John A. Creighton Medical College, Omaha, 1910, formerly county physician, aged 49, died Nov 27, 1935, of carcinoma of the bladder

Alexander Hill Neagle, Elmira, N. Y., Columbia University College of Physicians and Surgeons, New York, 1918, aged 44, died, Nov 26, 1935, of pulmonary tuberculosis

Charles Warren Dennis, Middletown, N. Y., Rush Medical College, Chicago, 1883, aged 77, died, Dec 9, 1935, of arterio-sclerotic heart disease and bronchopneumonia

Horace Henry Hosford Ⓢ St. John, Edma, Mo., Barnes Medical College, St. Louis, 1900, aged 84, was found dead in bed, Dec 17, 1935, of valvular heart disease

John Edgar Swarts, Canton, N. Y., Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1919, aged 39, died Dec 13, 1935, of cirrhosis of the liver

John Keen Young, Hot Springs National Park, Ark., University of Nashville (Tenn.) Medical Department, 1909, aged 55, died, Nov 7, 1935, of angina pectoris

Henry Edward Dunham, Minneapolis, Hahnemann Medical College and Hospital, Chicago, 1889, aged 73, died, Dec 7, 1935, in Rochester, of coronary sclerosis

Sarah Marie Washburn Alexander, La Valle, Wis., Woman's Medical College, Chicago, 1890, aged 88, died Dec 5, 1935, of arteriosclerotic heart disease

Frank Warren Hudson, Troy, Ohio, Eclectic Medical College, Cincinnati, 1929, aged 33, died, Nov 20, 1935, of pulmonary tuberculosis and brain abscess

PLAPAO LABORATORIES, INC

F J Stuart and His Quack Rupture-Cure Device Debarred from the Mails

For more than a quarter of a century one F J Stuart of St Louis has been selling what was essentially a piece of adhesive plaster and a little ointment as a cure for rupture. Purchasers have been obtained through fake analyses and misleading testimonials, and in the past persons who were unwise enough to answer Stuart's advertisements found their letters in the hands of letter brokers, to be rented or bought by any other quacks in the rupture-cure field.

Stuart's device used to be called the "Adhesive Hermal Plaster Pads." The name was changed many years ago to "Adhesif Plas tr-Pads" and still later to "Adhesif Plapao-Pads for Rupture." The original name of Stuart's quackery was the Stuart Plaster Pad Company but many years ago he changed that name to Plapao Laboratories, Inc. The reason for the change in name we do not know but it occurred after some unenviable publicity had been given to the Stuart Plaster Pad Company due to action taken by government officials under the National Food and Drugs Act. Stuart's original claims before the Food and Drug officials hailed him into court were frankly and blatantly fraudulent. The advertising stated definitely "Stuart's Adhesive Plaster-Pads Cure Rupture." After his brush with the Food and Drug officials, this advertising was changed to "Stuart's Plas tr-Pads Give Quick and Permanent Relief," which of course meant the same thing but didn't say it quite so crudely. In fact, the word "cure," which occurred all through the very early Stuart advertising was eliminated and some more euphous but equally misleading phrase used in its stead.

This department of THE JOURNAL carried an extensive article on the Stuart quackery in the issue of Feb 10, 1912. At that time it was brought out that Stuart's device which, according to Stuart would do in a few days what some of the most skilful physicians and surgeons are unable to accomplish in weeks or even months was to all intents and purposes a strip of adhesive plaster with a small pad containing a simple ointment. The padded portion of the plaster was to be placed over the hermal opening and the plaster itself applied to the skin. Then if Stuart was to be believed—which he was not—the plaster would contract strengthen and restore the 'stretched-out and weakened muscles' and the hernia would be cured.

THE JOURNAL article brought out the fact that the Association's chemists after analyzing the ointment which comprised the "patent medicine accessory to the device reported that it was essentially lanolin to which tannic acid had been added the whole perfumed with oil of pine needles. The same article also disclosed that while Stuart's advertising gave the impression that trusses for rupture are harmful and worthless, yet at the same time he was carrying a line of trusses that he was willing to sell to those who were unwilling to buy his Plapao Pads.

In the article too, some of Stuart's testimonials were discussed. One which Stuart played up at some length purported to be an analysis issued by 'Dr' A B Griffiths of London England. Stuart reproduced the Griffiths 'analysis' in fac simile. It was shown in the first article that Griffiths was himself a faker who made a business of furnishing analyses for various classes of medical humbugs at one guinea (\$5) each. The older article also gave the results of investigations of testimonials published by Stuart showing that individuals who had according to the testimonials been claimed to have been cured of their hernia were, in fact not cured. The article quoted too from Stuart's advertising showing that while he made the claim that the utmost privacy was always maintained in all of his correspondence and business relations nevertheless one of the largest letter-brokers in the country listed for sale or rent over 17,000 original letters that had been sent to the Stuart Plaster Pad Company.

Following the 1912 article there were published references to two cases in which the Stuart device had been alleged to have

produced either death or serious injury. The first concerned the case of a woman who brought suit against the Plapao Laboratories to recover damages for the death of her husband from a strangulated hernia after using Plas-tr-Pads. The man had been suffering from rupture for some years and had worn steel or elastic trusses. Having seen some of the Plapao Laboratories advertisements, he ordered the Plas-tr-Pads applied them on the 15th of the month and on the 19th died from strangulated hernia. The other case was that of a woman who also purchased Plapao Pads and applied them as directed and after using them for some time, was compelled to call a physician because of the pain. The physician testified that he found an inflammatory condition with sloughing and gangrene and peritonitis. While the woman was awarded \$3,000 damages in the trial court, the judgment was reversed on a technicality when it was carried to the Court of Appeals.

In May 1935 the Plapao Laboratories, Inc, and F J Stuart were called on by the Post Office department to show why a fraud order should not be issued against them. A hearing was held in July and occupied four days. The transcript of the record contained nearly 700 pages exclusive of exhibits. In addition, Stuart's attorneys were granted permission to file a brief subsequent to the hearing, and this was done and given

TRUSS USERS

STUART'S ADHESIF PLAPAO-PADS are patentably different—being mechanico-chemico applicators—made self-adhesive purposely to keep the muscle tonic called PLAPAO continuously applied to the affected parts and to minimize danger of slipping and painful friction. The fabric is soft as velvet and being adhesive—

—clings closely to the body—

—without straps, buckles or springs

Easy to apply comparatively inexpensive and comfortable

For almost a quarter century stacks of sworn testimonials from many different countries report success without delay from work. Process of recovery natural after which no further use for a mechanical support. Test of the remedial herbal factor PLAPAO sent you. No charge for it now or ever. Write name on coupon NOW, and mail TODAY.

due consideration by the Office of the Solicitor of the Post Office Department. After going over all the evidence in the case, the Acting Solicitor Mr W E Kelly, declared that Stuart's scheme was one for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises. Mr Kelly recommended that the Postmaster General issue a fraud order against the Plapao Laboratories, Inc, and F J Stuart debarring them from the mails. This was done on Sept 6, 1935.

The Acting Solicitor's memorandum to the Postmaster General is an extensive record of some forty-eight pages and contains much detail that need not at this time be gone into. It was brought out that F J Stuart started the fraud in 1907 under the name Stuart Plaster Pad Company. In 1910 he incorporated it under the laws of the state of Missouri as Plapao Laboratories, Inc. At the time of the hearing the concern was a family affair, the officers being Frank J Stuart, President Treasurer and General Manager Ruth L Stuart (daughter of Frank J.) Vice President, and Mrs Stuart (wife of Frank J.) Secretary. Stuart himself was said to own all of the \$50,000 capital stock. The gross receipts at the time the Post Office authorities looked into the business were between \$50,000 and \$60,000 a year but in more prosperous years had amounted to as much as \$250,000 a year. Mr Kelly's memorandum also states that the concern has been advertising in about twenty-five newspapers, placing the advertisements through an agency the Commercial Advertising and Exploitation Company,

which also was owned by Stuart. In addition to the quackery involved in this case, the Plapao Laboratories, Inc., also sold artificial limbs, braces, abdominal supporters, suspensories and similar articles.

The memorandum then goes on to detail the means by which Stuart was able to catch his victims belittling ordinary trusses, warning the public against them, elaborating on the proposition that the principle on which the truss works is wrong, while the Plapao Pads were right, etc. Stuart still had his 'patent medicine' adjunct, the ointment that was supposed to heal the rupture and which, of late years, he has called "Factor Plapao." This was supposed to be rubbed into the skin over the rupture before applying the Plapao Pads. The Pads themselves are described in the Solicitor's memorandum as follows:

"Stuart's Adhesif Plapao-Pads consist of a strip of adhesive tape about sixteen inches long and two and one-half inches wide which broadens out to an irregularly circular section about four and one-half inches in diameter and about one and three-fourths inches from one end of the strip. To this roughly circular part is attached half of an ovoid shell made of some hard substance approximately two and three-fourths inches long by two inches wide, which is the equivalent of the pad on an ordinary truss. This ovoid shell is pierced upon the surface which is applied to the body by a five-sixteenths of an inch opening through which its contents, consisting of the Factor Plapao, is supposed to flow onto the skin of the wearer, this 'Factor Plapao' being the salve contained in the shell.

The memorandum brought out, further, that the ointment that was supposed to heal the rupture was still essentially lanolin with astringents (tannic and gallic acids) making up the bulk of the medicament. It appeared, however, that occasionally the so called Factor Plapao contained red pepper and even oil of mustard. The memorandum also made clear that Stuart attempted to evade responsibility by stating in a circular that was sent with the device after he had the victim's money, that the company would "assume no responsibility for the improper application or use of Plapao Pad." It also showed that while the advertising literature led the ruptured to believe that trusses were dangerous or worthless and that the Plapao Pad was the only real cure, the purchaser found after paying for the device and getting the instructions for its use that it was practically essential in every case also to order a belt or a truss.

The government put on the stand as experts two reputable physicians, one the Acting Surgeon-General of the United States Army and the other a prominent surgeon from the District of Columbia. Both of the men had had long experience in dealing with various kinds of ruptures and were thoroughly familiar with the proper methods of treatment. They testified, after thoroughly familiarizing themselves with the Plapao device and the constituents of the salve, etc., that the thing was worthless as a cure for rupture. These physicians showed that it was quite impossible to cure a hernia by rubbing a counter-irritant on the skin over the hernia.

Stuart put on two alleged experts, both of them, it appears from the memorandum, homeopaths. One of these men claimed that he had treated an Iowa senator for ventral hernia with the Plapao Pads. He would not, however, declare under oath that the senator was cured, but did express the opinion that his condition was improved. The Solicitor's memorandum states that the cross-examination of this witness showed that he had a very inaccurate and uncertain recollection of the case and that his statement could not be taken as correctly reporting either the nature or the cause of the hernia suffered by the senator or the character and results of the treatment. The same physician also admitted that he had never since used the Plapao Pads on any of his own patients, and he refused to express any opinion as to the efficacy of the Plapao Pads when used for femoral or inguinal hernias. In fact, the Solicitor pointed out that the testimony of this physician who appeared as an expert for Stuart flatly contradicted the representations contained in Stuart's literature.

The other expert produced by Stuart testified on direct examination that he had observed good effects where he had applied Plapao Pads to persons who had purchased them through one of Stuart's demonstrators at a local hotel. The doctor stated that hotel employees had an arrangement whereby purchasers of the Plapao Pads were sent to him (the physician) to have

the Pads applied. The memorandum brings out that on cross examination this physician displayed and confessed ignorance of the anatomical structures involved in hernia, both as to their location and function. When questioned concerning Poupart's ligament, he is said to have stated that he had heard of it! He was unable to answer a question as to where Poupart's ligament is located.

Stuart also brought to the hearing as witnesses laymen who were to testify as to the efficacy of the Plapao Pads. They came from Alton, Ill., and Bloomington, Ind. All of the witnesses, however, wore belts or some other retaining device in addition to Plapao Pads! The government put on the stand some lay witnesses who had used Plapao Pads without any beneficial results, and one of the witnesses had been taken ill while wearing a Plapao Pad and had to be hastily removed to a hospital and immediately operated on.

The memorandum refers, also, to the fact that Stuart also advertised that he had a cure for irreducible rupture that was 'successful when everything else failed.' This also consisted of a device with a 'patent medicine' adjunct. The latter, instead of being called 'Factor Plapao,' was called 'Abaco,' but it had practically the same composition as Factor Plapao. The only difference was that while the Factor Plapao was supposed, when rubbed on the skin, to cause the muscles to come together and close the opening, the Abaco, when rubbed on the skin was said to break up the adherent, incarcerated, irreducible bunch! There is much more in the Solicitor's memorandum regarding this fraud, but sufficient has been said to indicate the character of the swindle that Stuart has carried out for so many years. On Sept. 6, 1935, the mails were closed to the Plapao Laboratories, Inc. and F. J. Stuart and their officers and agents as such.

After the fraud order had been issued against the Plapao Laboratories, Inc., and F. J. Stuart, Stuart attempted to evade it by sending out equally fraudulent material under the old name of his quackery, the Stuart Plaster Pad Company. As a result, the Solicitor for the Post Office Department on November 13, 1935, recommended that a supplemental fraud order be issued against the Stuart Plaster Pad Company. The Postmaster General issued such an order on November 15. A further supplemental order was issued on December 21 to cover the name Plapao Company.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE: The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

Alberty's Organic Phosphate Pellets—Alberty Food Laboratories, Hollywood, Calif. Composition: Calcium iron sodium potassium and phosphorus compounds, in milk sugar. For building nerve tissue. Fraudulent therapeutic claims.—[N. J. 23017, April 1935.]

Dakota Jack's Cowboy Liniment—Dakota Jack White Moon Remedy Co., Louisville. Composition: Essentially a volatile oil such as turpentine oil, ammonia (1 per cent), chloroform, linseed oil and water. Fraudulent therapeutic claims.—[A. J. 23010, April 1935.]

Instant Alberty's Food—Alberty Food Laboratories, Hollywood, Calif. Composition: Essentially dried milk and plant material including starch, body builder, etc. Fraudulent therapeutic claims.—[N. J. 23020, April 1935.]

Red Monk Tonic—Red Monk Medicinal Wine Co., Los Angeles. Composition: Essentially caffeine, a small amount of quinine compound with alcohol, glycerin and water. For blood and nerve disorders. Fraudulent therapeutic claims.—[N. J. 23024, April 1935.]

Almo Tonic—Hallstead Mfg. Co., Hallstead, Pa. Composition: Essentially laxative plant extract, alcohol (28.6 per cent by volume) and water. For nerve, kidney and liver disorders. Fraudulent therapeutic claims.—[A. J. 23024, April 1935.]

Correspondence

TESTS OF RENAL EFFICIENCY

To the Editor —I am greatly interested in what Dr R H Freyberg had to say about the choice of tests of renal efficiency in *THE JOURNAL*, Nov 16, 1935. Undoubtedly the Newburgh-Lashmet concentration test and the urea clearance test accurately measure kidney function, but for the practitioner they are unwieldy. The first test requires thirty-eight hours under a carefully selected diet with 1 Gm of salt added and the severe restriction of fluids to 780 cc in twenty-four hours. The collections of urine are taken over this period of thirty-eight hours. The urea clearance test requires three hours of the patients' and attendants' time and the added expense of chemical analyses. Obviously such involved procedures are not adaptable to ordinary medical practice.

A hazard of the Newburgh test is that with such severe fluid restriction, patients with moderately advanced Bright's disease may be precipitated into uremia. Dr Harry H Derow at the Beth Israel Hospital has abandoned the test for this reason.

I still believe that the fifteen and thirty minute phenolsulfonphthalein excretion test, which requires one hour of the patient's and doctor's time and no laboratory expense, is the test of choice for the practitioner.

EARLE M CHAPMAN, M.D., Boston

BLOOD TESTS FOR PATERNITY

To the Editor —In *THE JOURNAL*, Dec 21, 1935, page 2096, a correspondent requested information concerning the age of an infant when agglutination tests for paternity should be undertaken. The answer stated that, "in cases of disputed paternity, reliable results can be obtained even when the blood of newborn infants is tested" and that the incomplete development of the blood group at birth did not interfere with its determination. I should like to qualify these statements by pointing out that certain phases of the development of the blood group in the young infant often necessitate postponement of the tests before they can be accepted with the finality required for forensic purposes.

In a study entitled "Iso Agglutinins of the New-Born" (*Am J Dis Child* 36:54 [July] 1928) I presented the results of an investigation which strongly suggested that iso-agglutinins detected in the cord blood and in the peripheral blood of the infant for a variable period after birth were in large part derived from the mother through the medium of placental transfer. In twenty-seven of forty-one cases in which iso-agglutinins were noted in the blood of the umbilical cord re-examination within ten days revealed either a diminution in their titer or their complete disappearance. The blood group was later definitely established with the elaboration by the infant of iso agglutinins and receptors of its own manufacture. The significance of this sequence of events was illustrated in two cases encountered in this study. In these infants the cord blood revealed the presence of a and b iso-agglutinins and the complete absence of agglutinogens, so that the blood, like that of the mother, could be classified as group O. Re-examination of the blood of these infants within ten days failed to reveal any trace of either iso agglutinin. A and B agglutinogens on the other hand made their respective appearance at this time. With later retesting, the acquisition of the corresponding b and a iso agglutinins was in evidence and the blood groups could be completely classified as A and B. In other words the blood of the two infants at birth fulfilled the requirements of group O by tests for receptors and iso-agglutinins, to be replaced subsequently by their own blood groups A and B. These are instances in which the iso-agglutinins that disappeared did not

properly belong to the infant but had presumably originated by placental transmission from the mother. Changes of this character are probably not uncommon and must be borne in mind when blood group determinations are utilized for medicolegal purposes. If blood tests to exclude paternity had been carried out on these two infants at birth they would have satisfied the requirements of group O. With the subsequent dropping out of one or both iso-agglutinins and the development by the infant of its own specific agglutinogens and their associated iso-agglutinins, the problem of paternity is reopened for discussion. Such a train of events is of special significance when the permanent blood group contains at least one of the receptors, in which case more precise linkage to a parent may be established.

When an important decision, such as the exclusion of paternity, is to be rendered on the basis of blood group determination, it is urgent that the results in the instance of the infant be evaluated in the light of these observations. The conclusion which this study justifies is the expediency, from the medicolegal standpoint, of deferring these tests for a minimum period of at least two weeks, so that the development of the blood group by the young infant may be assured. Particularly is caution to be exercised when the blood at birth conforms to that of group O. When it is anticipated that paternity will be disputed, frequent retesting from birth is desirable in order to record the development of the blood group factors. It is possible, perhaps, that these restrictions apply as well to the M and N agglutinogens of Landsteiner and Levine, which have recently been subjected to genetic analysis.

COLD ALLERGY OR PRURITUS HIEMALIS

To the Editor —I am treating a man who is 60 years old. His past history is in every respect negative. For the last twenty years he has had an intense pruritus. The itch sets in with the cold season and disappears year after year with the onset of warm weather. Examination of the patient by numerous physicians was always negative. No skin treatment or internal medication brought any relief. Would you consider this a case of cold allergy? What would be the treatment? Please omit name.

M.D. New York

ANSWER —The description given does not state whether the itching is periodic or constant, whether it occurs only after chilling, or what parts of the body are affected. It seems sufficient, however, to exclude pruritus due to toxic conditions, icterus, some form of lymphoblastoma, internal carcinoma, malaria, diabetes, tuberculosis, skin parasites and nephritis. These can hardly be imagined operating each winter for twenty years and ceasing to cause itching in the spring time. Four possibilities present themselves: (1) pruritus hiemalis (2) bath pruritus, (3) chilblains, (4) cold allergy.

Pruritus hiemalis comes on with the first cool weather and persists until the advent of warmer weather in spring, growing worse as the temperature falls and better as it rises. It is more pronounced on undressing morning and evening and for an hour or two after retiring. During the day there may be little irritation. It is quite general but often is more intense on the anterior inner sides of the thighs on the calves about the joints and on the forearms. The only skin lesions are the secondary changes due to scratching. It is ascribed to a naturally sensitive skin deficient in fat and perspiration and therefore too dry in the dry air of winter. Coarse woolen underwear encourages it. The remedy is avoidance of soap and hot water in bathing and frequent applications of oil or ointment, particularly right after bathing before the skin is wholly dry. Measures should be taken to keep the air moist in the patient's rooms.

Bath pruritus is the result of drying of the skin by too generous use of soap and hot water in the dry air of winter and

steam heated apartments. It is most apt to occur on the legs, where the skin is often seen to be dry and scaly. Another favorite site is the upper part of the back, which is subject to a peculiarly stinging itch on retiring after a hot bath. It is better to bathe in the day time, for the itching seems to be less when the patient dresses after the bath and keeps his mind occupied. Soap should be used only on the hairy parts, feet and hands. Luke warm water followed by cold water is best.

Chilblains would affect only certain of the extremities in which the cutaneous circulation has been injured by freezing or severe chilling. The part is bluish red, moist and cold. The itching can be alleviated by compression for a short time with a wide elastic band, by exercise of the blood vessels by means of warm baths followed by a short cold douche and vigorous massage toward the center of the body with some oil or fat, by the faradic current, or by coating the part with successive layers of paraffin and then stripping them off. If the feet are affected, as is usual, loose warm footwear is imperative. No garters should be worn.

Cold allergy is manifested by attacks of swelling and congestion of the part, usually an extremity, after exposure to cold, accompanied by a tingling sensation. Soon after this, throbbing and burning sensations occur in the part affected and a general reaction comes on, with flushing of the face, rapid pulse, low blood pressure and sometimes fainting. If return circulation from the exposed part is prevented by a tourniquet, no general reaction occurs until the tourniquet is released, showing that the reaction is due to some substance, resembling histamine, that is separated or produced in the tissues by the chilling. The general reaction passes off in about a half hour, but the local reaction may continue for twenty-four hours. This hypersensitive condition can often be cured by daily graduated cool baths, just enough to cause a slight reaction.

DERMATOPHYTOSIS

To the Editor—I am suffering from a severe attack of epidermomycosis on my fingers and hands. I have used to date iodine solution as suggested by the Philadelphia Skin and Cancer Clinic sulfur ointment modified Whitfield's ointment balsam ointment taralba (Stearns' distillate of coal tar) Upjohn and crude coal tar and zinc oxide. I cleared up the first attack (July 15, 1922) but the last remission (August 13 to the present) seems too stubborn. Kindly suggest further treatment. The skin becomes dark red blisters form and break, leaving raw pits the skin peels under the new skin are more blisters. There is considerable itching which is controlled by tar ointment. M D Wisconsin

ANSWER—The treatment of dermatophytosis calls for resourcefulness on the part of the physician. The fungi seem to be as versatile in their cultivation of resistance to medication as they are in causation of sensitivity of the patient.

An examination should be made for fungi in the tops of the vesicles. The tops should be removed, placed bottom up on the slide, covered with 10 per cent potassium hydroxide, a cover glass put over the preparation, and the slide placed in a humidior, a petri dish in which there is a small piece of moist blotting paper. At intervals search for fungi should be made by means of the high dry lens. If fungi are not found within seventy-two hours, the case may be a local sensitization caused by the previous ringworm infection. In that event a trial of soothing treatment is indicated, cool wet dressings of solution of aluminum acetate 1:16 in water followed by calamine lotion. After the blisters cease to form a zinc oxide paste, zinc oxide and starch, 25 per cent of each in rose water ointment, may be applied once a day.

If fungi are found, the cool wet dressings of solution of aluminum acetate should be followed by a Whitfield ointment, 3 per cent salicylic acid and 6 per cent benzoic acid in rose water ointment applied twice a day after the cool wet dressings. Bathing is allowed, soap suds being used copiously on the feet but not allowing them to soak. The feet are dried and the ointment is applied. If preferred, the parts may be painted once daily with 1 per cent solution of potassium permanganate, allowed to dry, and a generous application of talcum powder applied with a cotton pad between the toes to prevent rubbing and perspiration. When the skin becomes too dry, the painting is stopped and the Whitfield ointment applied. This may be made stronger, of course, if thought necessary.

Roentgen treatments, one-fourth erythema dose (75 roentgens) once a week, will often clear up such an eruption whether it be due to sensitization or to ringworm infection. After the eruption has subsided, soothing applications should follow, calamine lotion or zinc paste, for about three weeks. After this, if the case is one of ringworm infection, Whitfield ointment, a salicylic sulphur ointment or some active fungistatic should be used to prevent recurrence. If this effort is successful, the medication may be gradually lessened. It should be kept up to some degree for at least one month after apparent

cure. It is understood, of course, that roentgen treatments should cease after two full erythema doses (600 roentgens) have been given and that all irritating applications must be avoided during and for three weeks after the use of the rays.

HARDNESS OF HEARING

To the Editor—I am 38 years of age, graduated from medical school in 1920 eighth in my class of 186 have worn glasses since 1917 for a myopia and astigmatism and had apparently good hearing during my college days. In November 1925 I contracted a good dose of bilateral mumps and was tied up for about two weeks and had a slight case of diphtheria in April 1922. In June 1920 just after graduating I had the tonsils and adenoids removed. In my early life and up to about 1912 I had many attacks of tonsillitis and quinsy. I believe that I first noticed deafness about eight years ago but of course it was slight and I did not think anything about it until the past two years when it has become quite noticeable to myself and my wife and it naturally is a handicap in practice unless the patient speaks a little louder than usual. In medical meetings at present I am lost and really do not gain anything by attendance. A year ago I went to Philadelphia and consulted a prominent otologist who is a professor in my medical school. He gave me a rigorous examination. The hearing tests with tuning forks were confirmed by the audiometer. The hearing on the right side was seriously impaired and the hearing loss in sensation units was 48 per cent on the left side a loss of 24 per cent. Neurologic (Barany) examinations suggested impaired hearing due to causes beyond the middle and internal ear. The rotary and caloric stimulations of both horizontal semicircular canals were greatly impaired. The vertical canals of both sides were blocked in the vestibuloocular tracts also of the vestibulo cerebello cerebral tract of the right side. This reaction to the test indicated some pathologic change where the stimuli enter the brain stem to the ocular nuclei in the posterior longitudinal bundle on a level with the middle cerebellar peduncles. Perhaps there was an unrecognized middle ear and mastoid infection or the toxins resulting from the mumps produced this pathologic change along the floor of the meninges such as a serious meningitis might cause. He suggested neurologic, roentgen and ophthalmologic examinations. All these tests were done. Roentgen examination proved negative for both mastoids except that there was a slight darkening of the periphery of the right mastoid. Otherwise both were clear. The neurologist gave a negative report. The eye report was O D —1.00 —0.75 cy ax 90 O S —2.25 —0.75 cy ax 97½. I had my glasses made according to that prescription which was practically identical with my former one. To my personal history I can add that I never had a discharging ear nor do my parents remember such. Both my parents are deaf my mother becoming so at about 20 years following a cold from a rain storm while my father has been that way for the past ten years he is now 62. There is no history on my father's side of deafness but my mother's father was deaf (He stated that he contracted it working in a locomotive boiler works?) but there is also another son who is very deaf. My father now wears an electrical device over his ear as he states that bone conduction does not seem to help him my mother is too self conscious to wear one but hears only if one speaks very loudly. She watches the lips too. Urinalysis is negative the Kahn reaction is negative and a blood count is as close to normal as possible. Is there any treatment you can suggest that might be helpful or in your opinion is treatment hopeless? In such case would you advise a hearing device as bone conduction? I recall hearing of a woman who is more deaf than I yet when she suggested a hearing device to her otologist he emphatically told her that one would only make matters worse. I cannot understand that attitude. Recently I was told of a physician using indirect diathermy in treating deafness. Is there any value or harm in this method? I have been a great follower of your department in *THE JOURNAL* and have saved many an article which has been helpful. Kindly omit name if printed. M D Pennsylvania

ANSWER—It is quite unlikely that any form of treatment will have much effect in this case. On the other hand, it is possible that the hearing may remain in its present status indefinitely. With reference to electrical hearing aids, one may say that, if the bone conduction is good, electrical hearing devices, especially those with a bone conduction attachment, in many instances aid the patient greatly. There is no statement here with reference to the bone conduction, so it is impossible to say whether in this instance the hearing device will afford benefit. It will be necessary to have the bone conduction tested and then if it is fairly normal, or perhaps even lengthened, to try out one or several of the aids now on the market. It is advisable to buy one only if the patient finds that there is a material improvement when the apparatus is being used, but he must be careful to keep the eyes closed at first in testing the instrument in order to be sure that he is not doing some lip reading at the time and that the improvement if any, is actually due to the appliance then being tried. If the bone conduction is very materially shortened, it is doubtful whether any appliance will be of assistance, but the ordinary 1 meter hearing tube used with one end in the patient's ear and the larger funnel shaped end used by the speaker, is often of material assistance. Many persons abstain from using the tube because of inconvenience in carrying it about and the embarrassment it causes many persons when using it. So far as diathermy is concerned, we have never seen any data to make one believe that this method of treatment is of any avail.

HIRSCHSPRUNG'S DISEASE

To the Editor—A girl baby aged 16 months presents the signs and symptoms of early Hirschsprung's disease. The baby has one brother who is suffering from the same condition. What is the present status of medical and dietary treatment? What is the status of surgical treatment as reported by Dr Rankin, viz., resection of sympathetic nerves? When is this surgical treatment indicated? Can anything be done to arrest the further progress of an early condition?

SAMUEL C. YACHIN, M.D. Lyndhurst, N. J.

ANSWER—Remedies of various kinds have been used in the treatment of Hirschsprung's disease without material benefit. Drugs intended to relieve the spasticity of the bowel, such as belladonna or atropine, have not yielded results. Cathartic drugs are usually without much effect, produce colic and tend to make the condition worse. Liquid petrolatum given by mouth acts as an intestinal lubricant and sometimes assists in the evacuation of hard feces. Enemas of olive oil, plain water or physiologic solution of sodium chloride tend to prevent stasis and are used to give the patient relief.

So far as the dietary treatment is concerned the patient should be given water in abundance and a nutritious diet that contains a minimum amount of residue and cellulose material. In an infant of 16 months, milk with addition of a malt preparation or Kellor's malt soup, and fruit, preferably stewed, vegetable soup carefully pureed, and sweets, as honey, jelly or jam, maple syrup or corn syrup with white bread, are indicated.

Hirschsprung's disease is due to an achalasia, a failure of the colonic musculature and of the rectosigmoidal sphincter to relax. A Berg (Libman's Anniversary Volumes, volume 1), in reviewing five cases of Hirschsprung's disease in which ganglionectomy and ramisection was performed, found that the constipation was relieved, though the caliber and size of the bowel were not influenced by the operation. Consequently the patients are still liable to suffer from a complicating volvulus. Berg concludes that, if the occurrence of volvulus is to be averted, the dilated, elongated loop of the intestine must be resected. Fred W. Rankin and James R. Learmonth (*Ann Surg* 92:710 [Oct] 1930) advise that ramisection be performed before profound atony or extensive atrophy has occurred. Alfred W. Adson (*Ann Int Med* 6:1044 [Feb] 1933) reports that sympathectomy has been performed without a fatality in eight cases of Hirschsprung's disease occurring in children and in two cases of acquired megacolon in young women. Adson says that his patients had symptomatic relief and that although the colon was reduced in size it did not become of normal dimensions after the operation.

Most clinicians, particularly surgeons, advise that operation be performed relatively early before extreme dilatation of the colon and loss of weight and strength have occurred. Early operation, if successful, would diminish the occurrence of volvulus and intestinal obstruction.

In a case of genuine Hirschsprung's disease, no procedure short of surgical intervention along the lines already indicated will arrest the progress of the disorder.

TREATMENT OF ANGIOMA

To the Editor—Please let me know the best method for treating a case of capillary angioma in a 3 months old baby boy. The angioma is about 2.5 cm in diameter and is located over the parietal region of the scalp. There is some hair growing on the area of angioma. It is more pronounced now than before. What would be the best age for treatment now or later? Will carbon dioxide snow remove the tumor satisfactorily without destruction of the hair follicles? Will electrical coagulation or quartz light be less apt to injure the hair growth in the region of the tumor?

M. D. Washington

To the Editor—I have a hemangioma case in a baby 13 months old. The hemangioma is 2½ inches in diameter is about one fourth inch thick (elevated above the skin) and is growing rapidly. There are of course several ways to treat this type of a condition but what I am interested in is to know whether or not it might be treated by the dry ice method. Are there any dangers in this method or any contraindications? What are the advantages of this method over others if any?

M. D. Washington

ANSWER—In view of the fact that the angioma mentioned in the first query shows signs of increase in size it would be well to treat it immediately. Carbon dioxide snow cautiously used will remove the tumor satisfactorily. Electrocoagulation would be more painful and unless very cautiously used might injure the hair growth. Quartz light (water cooled) is of questionable value in these cases. In the use of carbon dioxide snow the degree of reaction varies with the pressure and the duration of the application. The duration of the freezing is the most important factor. At the first application the freezing is usually from a period of five to ten seconds. Subsequent applications with increased pressure or greater duration depend on the amount of destruction desired and the degree of involution resulting from

the previous application. If the lesion is a simple capillary hemangioma (nevus araneus), application of the snow or the electric cautery to the central body, from which the capillaries radiate, often suffices. More than one application may be needed.

The hemangioma described in the second query can be treated by the dry ice method. Carbon dioxide snow is prepared from the liquid carbonic acid gas as it exists in high pressure tanks (Pusey, W. A. Principles and Practice of Dermatology, New York, D. Appleton & Co.) or from "dry ice" (Bloom, David A. Simplified Method of Preparing Pencils of Carbon Dioxide Snow, *Arch Dermat & Syph* 32:105 [July] 1935). The freezing is usually carried out for a period of five to ten seconds at the first application. Subsequent applications with increased pressure or greater duration depend on the amount of destruction desired and the degree of involution resulting from the previous application. The only danger in this method is over-treatment, but if the first application is cautiously given this will not take place. This method must be used with care in areas where the surfaces of the skin come in contact or where contamination may take place, as about the anogenital area. The advantage of this method over radium is the fact that less experience is required for carbon dioxide snow than for radium. Then, too, the snow is less expensive than radium. With good technique a desirable cosmetic result may be obtained. A greater degree of scarring usually results from the electro-surgical methods.

GALACTORRHEA

To the Editor—An obese woman aged 54 except for moderate dyspnea and palpitation associated with a chronic myocarditis has enjoyed good health in recent years. Her complaint now is an amenorrhea of five and one-half months duration morning nausea and a profuse milky secretion from both breasts. She supposes that she is pregnant. Pertinent facts in the past history are as follows. Her menstrual periods have always been normal from the menarche at the age of 14 until five years ago when she had an asymptomatic menopause the menses gradually becoming scanty and finally ceasing altogether. About eighteen months ago menstruation was resumed and was regular of the twenty-eight day type with no skipped periods or bleeding between periods. Each period was of four to five days duration. There was a scanty leukorrhea in the intermenstruum. She has had ten pregnancies only two of which reached term and both of these babies were small and died in the first few weeks of life. The patient is 5 feet 6 inches (168 cm) in height she weighs 220 pounds (100 kg). She is edentulous. The throat is normal. The thyroid is not palpable. There are no tremors. The skin is dry. The finger nails are brittle. There is eczema of the external auditory canals. The chest is clear. The heart shows moderate hypertrophy. The arteries are just palpable at the wrist. The blood pressure is 122 systolic 76 diastolic. Both breasts are large firm and present no nodules. The nipples are reddened and not retracted and an abundant milky fluid is easily expressed from each. The abdomen is very obese and pendulous. (The patient thinks this has enlarged recently as a result of the supposed pregnancy.) Pelvic examination is difficult because of the patient's size. The cervix is firm and lacerated and presents a small amount of mucoid discharge. The fundus is retroverted slightly enlarged to about the size of a lemon. No masses were palpated in the adnexa but this part of the examination was very difficult. The extremities are obese but slender at the ankles and wrists. Varicose veins are present. Blood examination revealed hemoglobin 90 per cent red blood cells 4,950,000 white blood cells 7,000. The Wassermann reaction is negative. The urine is entirely normal. I am unable to make a diagnosis in this case and should like any suggestions for further studies that might be made. I am particularly interested in the cause of the lactation. My opinion is that the cause is in the field of endocrinology but I am unable to locate the cause.

M. D. Michigan

ANSWER—The correspondent is probably correct in the opinion that the condition belongs in the class of endocrinopathy. It is an old observation that milk may appear in the breasts during puberty during menstruation, at the menopause and also if there are fibroids. This renders the sign unreliable in the diagnosis of pregnancy. Galactorrhea however is rare in the menopause and so also is a return of the regular periods such as occurred in this case. Naturally, one thinks at such times of some disturbance of the glandular apparatus, and as the two organs mostly involved in the milk secretion are the ovaries and the hypophysis (galactin), suspicion rests on them. A granulosa cell tumor of the ovary or a tumor of the hypophysis might produce the symptoms. The shape of the woman and her history indicate pituitary dysfunction and some dys-thyroidism. Investigation is recommended along these lines and it might also be interesting to make an Aschheim-Zondek test. The return and regularity of the periods point rather strongly to the ovary, their cessation leaves the hypophysis as the probable cause. Abdominoscopy might visualize the two ovaries, roentgen examination the pituitary.

Recently McNeile has recommended camphor in oil, 0.1 Gm daily intramuscularly, for three or four days to restrain the milk secretion after delivery. It might be tried in this case. If the patient is not pregnant, administration of estrogenic substance may have some effect on the galactorrhea.

PAIN AND TENDERNESS OF BREAST

To the Editor—A married woman aged 28 has two children both delivered normally the last one four and one half years ago. For the past three years she has been aware of an annoying sensation and tenderness to touch in her right breast. This at first was very slight but has steadily increased so that the breast has been tender and somewhat painful for the last three weeks. The left breast is normal on examination and also subjectively. The right breast on palpation suggests to the fingers a mass of knots and cords throughout. These are quite tender to touch. There is no disturbance in the contour of the breast, the nipple is normal, the axilla is free of glands and there is no history of a discharge from the breast. Pain is not related to the menses. What would you advise in this case and if it is cystic mastitis have you any knowledge of the efficacy of theelin?

M D New York

ANSWER—The case raises three main possibilities (1) unilateral mazoplasia, (2) cystic disease of the breast, either in its pure form or complicated by epithelial neoplasia, and (3) unilateral diffuse fibro-adenomatosis.

As regards the first possibility, it is possible but unusual for mazoplasia to affect only one breast. The fact that the pain is not related to the menstrual period is further evidence against this diagnosis. Cystic disease of the breast is possible in this case. The evidences against cystic disease are the conditions found on palpation. Usually in the breast of pronounced cystic disease there should be present one or more discrete, circumscribed, movable masses. When the cysts are sufficiently small, these conditions are absent. From the description given, the diagnosis of fibro-adenomatosis is most likely. Transillumination might help to distinguish between cystic disease and solid fibro-adenomatosis. The age of the patient favors the latter diagnosis. Tenderness also is more common in fibro-adenomatosis than in cystic disease.

The procedure to be adopted depends on the diagnosis. If the lesion is diffuse throughout the breast and there is no localized mass, it is safe to treat the patient conservatively and to defer operation. The lesion should be watched closely and, at the first sign of localization, an exploratory operation is immediately indicated. If the breast is a fibro-adenomatosis, no operation is indicated. Not infrequently in these cases it becomes necessary to perform an exploratory incision and biopsy in order to establish the true diagnosis of the lesion as between cystic disease and fibro-adenomatosis. This procedure, however, is usually deferred as long as the lesion is diffuse and there is no localized mass.

Theelin and other estrogenic preparations have been used in the treatment of painful breasts, and relief of pain has been reported. It is important to point out, however, that the relief of pain from these agents is limited to a certain group of cases, notably those in which the pain is bilateral and is related to the menstrual periods. It is rare to find relief of pain when the periods are either normal or long and very common when the periods are of short duration.

USE OF FROZEN MILK IN INFANT FEEDING

To the Editor—We are anxious to have your opinion on the use in infant feeding of milk that has been frozen. Does this frozen milk if heated to the boiling point and prepared for feeding in the usual manner produce an injurious effect on the otherwise normal healthy baby? Do you believe that heating the frozen milk to the boiling point causes the milk to return to a suspension that can be taken without ill effects by the average infant? Any information you can give us will be greatly appreciated.

ANN SULLIVAN Director Home Economics Washington D C

ANSWER—Milk as it freezes undergoes considerable physical changes, which are more pronounced the longer it remains frozen. Under no conditions is thawed milk exactly the same in every respect as unfrozen milk. Milk freezes at about 0.55 C, below the freezing point of water but it does not freeze completely, since the water freezes first and the solids form a more highly concentrated solution with a depression of the freezing point. Ice is formed at the bottom and sides of the vessel and a funnel-shaped cavity in the center is filled with liquid. The ice forms two layers one of cream the other of skim milk. The water thus freezes at first at the outside on the wall of the vessel, and the solids are forced toward the center, forming a more concentrated solution and this freezes at a lower temperature.

The fat rises and is partially churned when the milk freezes. The natural emulsion of fat is never completely restored after thawing, and the casein appears in flakes rather than in the original colloid condition. The fat content of the upper layers may be three times as high as the original amount, and much higher in the central portion of the milk than at the periphery. The emulsion of fat is destroyed more rapidly than the colloid condition of the casein. Other changes in the protein when

milk is held for a considerable period at a temperature of zero centigrade consists of a proteolysis of the casein and lactalbumin. Milk that has been frozen and then thawed is said to decompose more rapidly than otherwise. The thawed milk has a higher acidity than the original milk. Even at freezing temperature some bacteria continue to grow. It will not sour because the lactic bacilli do not grow at this temperature, but certain putrefactive and pathogenic organisms do.

Vomiting and not infrequently diarrhea may follow the feeding to infants of milk that has been frozen. The main cause of this is probably the separation of the fat, and even when the milk is thawed the fat globules coalesce and form a thick layer of butter fat, which may cause a gastro intestinal upset. If the process of thawing goes on slowly in a cool room, fewer changes remain in the fat emulsion.

FORMULA FOR ESTIMATING BASAL METABOLISM

To the Editor—Somewhere I have read that the basal metabolic rate can be estimated by a rather simple formula involving the blood pressure also a method involving the respiratory quotient. How are these estimations made? Are they sufficiently accurate to be of value? Please omit name.

M D Ohio

ANSWER—J Marion Read (Correlation of Basal Metabolic Rate with Pulse rate and Pulse Pressure, THE JOURNAL, June 17, 1922, p 1887) was the first to suggest the clinical use of a formula based on pulse rate and pulse pressure for the estimation of the basal metabolic rate. His first formula was

$$BMR = 0.683 (PR + 0.9 PP) - 71.5$$

in which P R is the basal pulse rate and P P the basal pulse pressure. This formula was modified slightly by him in 1924 (Basal Pulse Rate and Pulse Pressure Changes Accompanying Variations in the Basal Metabolic Rate, *Arch Int Med* 34 553 [Oct] 1924) and again by Read and Barnett in 1934, in the latter report (Read, J M, and Barnett, C W. New Formulae for the Prediction of Basal Metabolism from Pulse Rate and Pulse Pressure, *Proc Soc Exper Biol & Med* 31 723 [March] 1934) they suggested two formulas, one for each sex.

$$\text{For men, cal sq m per hour} = \frac{(P R) (P P)}{200} + 27$$

$$\text{For women, cal sq m per hour} = \frac{3 (P R) (P P)}{700} + 24$$

Rabinowitch has recently presented a detailed criticism of this method of estimating the basal metabolism (Rabinowitch, I M. Prediction of Basal Metabolism from Pulse Pressure and Pulse Rate, *Canad M A J* 32 135 [Feb] 1935). He concludes that practically it is possible to predict the rate of metabolism with a reasonable degree of accuracy in only about 50 per cent of the cases provided the pulse rate and pulse pressure are obtained under the same strict basal conditions as are necessary for the determination of the basal metabolic rate itself.

Conroe has also recently investigated the clinical value of attempting to estimate the basal metabolic rate from the pulse rate and pulse pressure. He too feels that the accuracy of the prediction is not sufficiently great to render the method a substitute for actual measurement of the basal metabolic rate by indirect calorimetry. However, if one wishes to use such an approximation, Conroe gives a convenient nomogram in his paper to simplify the calculation involved (Estimation of Basal Metabolic Rate from Pulse Rate and Pulse Pressure, *Am J M Sc* 190 371 [Sept] 1935).

ISOPROPYL ALCOHOL

To the Editor—I would appreciate your giving me the latest information on isopropyl alcohol its chemical properties pharmacologic action toxicology and therapeutics with special attention as to its antiseptic properties and whether it can be used as a sterilizing agent for the hands and instruments.

M D Texas

ANSWER—Isopropyl alcohol, or dimethyl carbinol $\text{CH}_3\text{CHOHCH}_3$, is a homologue of ethyl alcohol isomeric with normal propyl alcohol. It is a colorless liquid having a weak alcoholic odor somewhat resembling that of acetone. It is similar in most of its properties to ethyl alcohol.

A paper giving a synopsis of the then available data on the pharmacology of isopropyl alcohol appeared in the *Journal of Laboratory and Clinical Medicine* March 1923, p 382. The toxicology of the substance has been discussed by Macht (*J Pharmacol & Exper Therap* 16 1 [Aug] 1920). The British Pharmaceutical Codex (1934) contains the following statement in regard to the actions and uses of isopropyl alcohol "Isopropyl alcohol is twice as toxic as ethyl alcohol when given intravenously to cats, but it is sufficiently nontoxic for external and oral administration in small amounts. Inhalation of its

vapor has not been found to cause the defects on vision associated with methyl alcohol. Isopropyl alcohol is not potable and its ingestion produces a form of intoxication which resembles that produced by ethyl alcohol. In concentrations up to 50 per cent, applied externally to open wounds it allows healing to take place normally. It has been used for skin sterilization, also in antiseptic solutions for the throat. Isopropyl alcohol may be used for drying nitrocellulose, sugars, starches, animal or vegetable tissues, and for dehydrating histological specimens. It is used in cosmetics and the cheaper varieties of perfume and culinary essences."

We are informed that at the present time the Council on Pharmacy and Chemistry is considering the question of admitting isopropyl alcohol to New and Nonofficial Remedies as an agent useful in removing creosote from the skin and as a germicide for the sterilization of the skin as well as needles and syringes, particularly in connection with the administration of insulin.

In his report on the evidence submitted in favor of the use of isopropyl alcohol as a germicide, the Council's referee called attention to the lack of evidence for the effectiveness of the substance against the spores of *Bacillus Welchii*, *B. tetani* and *B. anthracis*. Although it was deemed a remote possibility that these spores might contaminate glass syringes in common use, the possibility of such contamination could not be denied. Hence, evidence on this point was requested but was not received. However, the evidence which was received did support the claim that isopropyl alcohol may be used for the reduction of the number of vegetative forms of bacteria on the skin, on hypodermic needles and on syringes. This evidence indicated that 10 per cent solutions of isopropyl alcohol are not germicidal, 20 per cent solutions are germicidal in some instances, and solutions containing 30 per cent or more of isopropyl alcohol regularly kill *Staphylococcus aureus* in five minutes at 20°C.

A review of experimental work on the germicidal properties of isopropyl alcohol by D. H. Grant was published in the *American Journal of the Medical Sciences* (166:261 [Aug] 1923).

TREATMENT OF HYPERTRICHOSIS

To the Editor—What are the various treatments and their relative status for hypertrichosis in the female? I am inquiring about a woman aged 23, presumably in excellent health but with coarse hair on her face, chin and upper lip, arms and body. She had a thyroidectomy three and a half years ago; her basal metabolism now being plus 4. She had a tonsilectomy in 1932 and an appendectomy five months ago. She has an infantile uterus for which she has received five injections of Progynon B in oil. She has an infection of both antrums. A physician told her that she has a tumor of the adrenal glands. How can one establish a diagnosis of this type and if so what are the results of adrenal surgery in cases of this type? Kindly omit name and address.

M D Wisconsin

ANSWER—Hirsutism in the female may develop as a result of any one of several conditions. Among these are arrhenoblastoma of the ovary and certain tumors of the adrenal cortex, disturbances of the anterior pituitary may also be involved although the role of the pituitary in the growth of hair is as yet poorly defined. The differential diagnosis may be difficult. R. T. Frank (*Proc Soc Exper Biol & Med* 31:1204 [June] 1934) has reported two cases of adrenal carcinoma in which tremendous amounts of estrogenic substance were excreted in the urine; this may possibly serve in differential diagnosis as such amounts of estrogenic substance are not otherwise known to be excreted except during pregnancy. A discussion of arrhenoblastoma of the ovary by Emil Novak appears in the *American Journal of the Medical Sciences* (187:599) [May] 1934. Removal of such tumors of the ovary is reported to lead to regression of symptoms. Surgery on the adrenal glands should not be undertaken unless definite tumor exists; subtotal adrenalectomy has been proposed for the treatment of hirsutism in the absence of tumor but there is no justification for this procedure.

CORRECTION OF POSTURE

To the Editor—Will you give me the name and address of the best place to take care of correction of posture? Please do not publish my name.

M D New Jersey

ANSWER—Poor posture may result from faulty habits but not infrequently it is secondary to organic disorders that lower the vitality of the individual. Gastro-intestinal disturbances, chronic infections of the nose and throat, defects of vision, malnutrition and fatigue may all be contributory factors.

Organic changes within the spine itself, such as those due to tuberculosis or to growth disturbances of the type described as vertebral epiphysitis may lead to permanent structural changes characterized by round shoulders or humped back.

For this reason every case of chronic poor posture should be carefully examined by a physician and roentgenograms of the spine taken before an attempt is made to correct the deformity.

The responsibility for directing the care of patients who have poor posture has been delegated to the orthopedic surgeon. Practically every orthopedic surgeon has available the services of a well trained physical therapist who understands the problem of prevention or correction of static deformities of the spine and extremities. A list of the men specializing in orthopedic surgery in any locality can be supplied to the physician requesting it by any of the following men:

Secretary of the Section on Orthopedic Surgery of the American Medical Association: Dr. Robert V. Funsien, University Va.
Secretary of the American Academy of Orthopaedic Surgeons: Dr. Philip Lewin, 104 South Michigan Avenue, Chicago.
Secretary of the American Orthopaedic Association: Dr. Ralph K. Ghormley, 102 Second Avenue S.W., Rochester, Minn.
Secretary of the Orthopaedic Section of the Pan American Medical Association: Dr. Edward L. Compere, 970 East Fifty Ninth Street, Chicago.

MUSCLE FATIGABILITY

To the Editor—A man aged 33, 5 feet 11 inches (180 cm.) in height of the large-boned type, weighing 285 pounds (93 kg.) complains of excessive fatigue. He is emotionally stable. His weight was 230 pounds (114 kg.) four months ago at which time he was definitely conscious of overweight and had the beginning of his fatigue. By diet and exercise the weight was gradually dropped to its present level. It seemed that after his weight began to drop below 220 pounds (100 kg.) his fatigue progressively increased. Now he complains of being tired at all times at the end of the day's office work; he can barely keep on his feet and he looks it. The blood pressure is normal; the basal metabolism is minus five (checked by different individuals and the record taken one month apart) and the blood sugar is 80. Everything else is normal and I have had my observations checked by two good internists. Thyroid was suggested for a try out and I gave 2 grains (0.13 Gm.) of a standard preparation three times daily for four weeks. This had no apparent effect on the fatigue but did increase perspiration and slightly accelerated the weight loss. The patient says he does not seem to have much choice—that when his weight is way up he feels puffed up like a swelling toad and has a little shortness of breath, and when his weight is where it is now he has fatigue that he cannot overcome. Suggestions will be gratefully received.

M D Virginia

ANSWER—The data are far too meager on which to base a diagnosis. Muscle weakness and fatigability are due to many causes, and the differential diagnosis of the various conditions is usually quite difficult. Myasthenia gravis, as well as other conditions, for example Addison's disease, should be considered. On the other hand, the patient may have simple fatigability. A suggestive symposium on some of the various forms of myopathy and the results of treatment in the different groups with fatigability was recently presented by Moersch, Boothby, Wilder and their associates (*Proceedings of the Staff Meetings of the Mayo Clinic* 9:589 [Oct. 3] 1934) which might furnish suggestions appropriate for the patient.

BURNING SENSATION IN MOUTH

To the Editor—Mrs. G. aged 64 complains of a severe burning sensation in the mouth of varying degree of intensity and apparently accentuated by certain foods, notably fruits. She cannot eat any of the citrus fruits because of the burning when attempts are made to eat them. Examination shows sclerotic, thrombosed or varicose areas on the sides and under parts of the tongue attended by redness about these areas and on the inside of the lower lip. There are no teeth, both upper and lower plates being worn. The buds on the back of the tongue are enlarged. The reaction as determined by the urine has been alternated between acid and alkaline without any appreciable change in the complaint. The blood pressure is 150 systolic, 90 diastolic. Treatment has consisted of potassium chlorate both in solution and as troches, Vinca and other perborates, potassium iodide and general systemic tonics. The condition has remissions and exacerbations without apparent relation to the diet. A Wassermann test has not been done. If you can help me out from this meager description it will be appreciated.

M D Ohio

ANSWER—Elderly patients complaining of burning sensations on the tongue and mucous membranes of the mouth accentuated by ingestion of certain types of food, are vexatious problems, as it is difficult to disclose even a trifling source of irritation. As in this case there usually are regions of the mucous membranes that have undergone various types of retrograde change. However, careful search should be made for some source of irritation. The artificial dentures are not above suspicion; the irritating effect of them being ascribed partly to the rubber content of the denture bases, partly to the heat-insulating effect of the closely applied plate and partly to the mechanical effect of the denture surface, especially if it is not absolutely clean. The dentures should be painstakingly cleaned frequently, in this case after each meal. During the acute

exacerbations it may be desirable to wear the dentures as little as possible, perhaps not at all. There are no more suitable mouth washes than the flavored perborates. Other than this the treatment is purely symptomatic and designed merely to relieve pain and uncomfortable sensations.

HERPES AND CHICKENPOX

To the Editor—In answer to a question in Queries and Minor Notes on the treatment of herpes (THE JOURNAL January 4 p 65) the statement is made that herpes simplex the cold sore is truly related to the virus of chickenpox a fact discovered by Professor Bokay many years ago. I believe this to be an error that should be corrected. It probably meant that the virus of herpes zoster is related to that of chickenpox (von Bokay J. Ueber den atiotogischer Zusammenhang der Varizellen mit gewissen Fallen von Herpes Zoster *Wien klin Wchnschr* 22 1323 1909).

E WILLIAM ABRAHOWITZ MD New York

ANSWER—It is true that von Bokay's original observations, which date back to 1888 related chickenpox to herpes zoster and not to herpes simplex. It is customary to differentiate strictly between these two eruptions. Herpes simplex produces no immunity and tends to recur indefinitely, neuralgic pains are absent, it leaves no scar, its virus is easily transmissible. The opposite of all this is true of herpes zoster. Nevertheless, both are admittedly virus diseases due to an irritative, infectious or toxic lesion in the posterior root ganglion, in the posterior column of the cord as well as in the peripheral nerves. In herpes simplex, lesions have been found in the sensory extramedullary ganglions supplying the area involved (Ormsby Diseases of the Skin, Philadelphia, Lea & Febiger 1934). Essentially both lesions are due to efferent nerve impulses liberating a histamine-like substance in the skin, which in turn is responsible for the vesicle and the surrounding destruction of tissue. In cases of herpes simplex occurring with pneumonia or cerebrospinal meningitis, degenerative and inflammatory changes were found by Howard and by Mallory and Wright in the ganglionic centers supplying the area. This virus disease is neurotropic the virus disease of herpes simplex is closely related to epidemic encephalitis.

MCCORMICK APPARATUS FOR ANALGESIA IN OBSTETRICS

To the Editor—In the Dec 21 1935 issue of THE JOURNAL an article appeared concerning the modified etheroil rectal analgesia by Drs Gwathmey and McCormick. I should like information as to where the McCormick apparatus for the instillation of the analgesia may be purchased with information as to price.

JAMES R JANNEY (fourth year student) Detroit

ANSWER—The McCormick apparatus for the rectal instillation of ether in oil is sold by the William H Armstrong Company Indianapolis, price \$20. The Asepto-syringe (4 ounce) is made by Becton, Dickinson & Co. Rutherford, N J price \$1.90.

EFFECTS OF LONG CONTINUED USE OF PHENOBARBITAL

To the Editor—What are the effects of the long continuous use of phenobarbital say from 3 to 5 grams (0.2 to 0.5 Gm) a day? What would be the effects on the sexual powers? MD Texas

ANSWER—Drowsiness and languor are symptoms of overdosage, dermatitis is a not uncommon complication. When phenobarbital is given in epilepsy, the indication is to lessen the dose or, if dermatitis occurs, to interrupt administration until it clears. Sexual power may share in the depression.

DIPHTHERIA TOXIN FOR SCHICK TESTS

To the Editor—Kindly advise me regarding the reliability of 'Diphtheria Toxin diluted ready for use in peptone buffered diluent for Schick testing'.

WALTER J SIEVSEN MD Chicago

ANSWER—The product in question may be regarded as reliable, provided it is approved by the United States Public Health Service.

NO RECORDS OF ALLERGIC SENSITIVITY TO TRYPARSAMIDE

To the Editor—I am interested in securing information and references about anaphylactic reactions to tryparsamide. I have a case showing a definite allergic sensitivity to tryparamide. MD Nebraska

ANSWER—In many thousands of cases there are no records of allergic reactions with tryparsamide. The case reported is therefore unusual.

Book Notices

Pediatric Treatment A Manual of the Treatment of the Diseases of
Infants and Children Designed as a Reference Work Especially for the
General Practitioner and Physicians Entering the Field of Pediatrics
By Philip S Potter A B M D F A A P Attending Pediatrician to the
Berkeley General Hospital Berkeley California Cloth Price \$5 Pp
578 New York Macmillan Company 1935

This book is well indexed but is not illustrated. Illustrations
demonstrating such manipulations as manual expression of
breast milk, applications of a yarn truss, and passage of a
nasal catheter for gastric lavage or gavage in infants would
enhance the descriptive value. A short well selected pertinent
bibliography appends each chapter. As intimated by the author
in the preface and as apparent from a perusal of the book, it
is elementary, the A B C of pediatric therapy, written especially
for the general practitioner but particularly suited for young
men starting out direct from the hospital. The treatment is
mainly that used in the home, which is of course somewhat
different from that employed in the hospital by interns. The
first five chapters are devoted to general therapeutic pro-
cedures, including emergency treatment (poisoning, with anti-
dotes, wounds and so on) and pharmacaceutics. Some attention
is given here to nursing procedures, so that the physician can
actually instruct the mother or attendant rather than order the
trained nurse, as in the hospital. The chapter on infant feeding
is rather brief, although general principles and specific milks
are mentioned. It would be advisable for the reader to consult
more extensive works in this rather specialized field. Diets
for older children are given in detail. They are conservative,
most new foods being started relatively late, so as to play safe,
because of the considerable difference of opinion as to when
various foods may be introduced. After the sections on nutri-
tion, metabolism and their disorders, and disease and abnormali-
ties of the new born, the treatment of disease is taken up by
systems, then treatment of communicable and infectious diseases,
and finally a section on additional prescriptions relating to
body systems. The book is essentially and principally on treat-
ment, little space being given to symptoms and diagnosis, which
is admirable in a book entitled specifically treatment, so many
others of these being given over to much diagnosis.

In a general criticism of the book there seems to be a ten-
dency to overtreat specifically instead of outlining general
principles, many trained pediatricians not using nearly so exten-
sive a therapeutic armamentarium. The prescriptions are often
somewhat complicated, much simpler administration of fewer
drugs probably would suffice. Some drugs are advised that
some good pediatricians frown on, such as castor oil, mild
mercurous chloride and silver salts in the nose. For example,
in the treatment of colds, cathartics, hot foot baths, hot drinks
(try to get young children to take them), Dobell's solution
menthol in petrolatum, or mild protein silver in the nose, a
rather complicated prescription, and in cervical adenitis out-
riments are mentioned but their psychic value is not. The
reviewer and his immediate preceptors use much simpler
therapy, except where it is necessary for the mother's psychic
rather than the child's physical benefit, but maybe he is wrong.
Proprietary names are given to many drugs and foods. There
is not much space or emphasis devoted to psychic therapy or to
mental hygiene, behavior disturbances and the like, which make
up considerable of pediatric practice. Generally speaking it is
a reasonably good therapeutic textbook of pediatrics for young
general practitioners, although it makes treatment more com-
plicated than is actually encountered in pediatric practice.

Der Geburtstod (Mutter und Kind) Von Dr Sigismund Peller. Paper
Price 5 marks. Pp 110 Leipzig & Vienna Franz Deuticke 1936

This monograph consists mainly of extensive statistical
records of the mortality of mothers and babies throughout the
world and particularly in Vienna. While there is considerable
discussion of the figures presented the subject matter does not
lend itself to a thorough review. In the first place, inter-
national statistics are not comparable, as was well proved by
the Secretariat on Health of the League of Nations in Geneva.
It published a chart giving sixteen reasons for the inability to
compare international statistics. The larger part of this work
refers to infant mortality, and the fear of depopulation is

stressed. The author starts out with the statement that nobody knows how many women die during childbirth. He guesses that from 40,000 to 50,000 die each year in Europe and that 20,000 die in the United States. (The United States census says that only about 15,000 die annually), from 6 to 8 per cent of the babies die aborting, and in spite of the enormous progress made in all branches of medicine, and of all the commissions and investigations and laws promulgated, maternal and fetal mortalities have not improved. Abortion claims a large and undiminishing number of women's lives, and hospitalization has not improved the conditions. Maternal mortality the world over varies from 2 to 18 per thousand. Leningrad has the lowest, India the highest, the white race less than the colored, mortalities are generally higher in the city than in the country (abortion), of cities, Berlin has the highest mortality in Europe, excluding abortion, while they are included in the other cities. The mortality of babies can be reduced not by better care during labor but by improving the social conditions of gravidæ. The author recommends pregnancy hospitals. While much can be done for the mother with good antepartum care, asepsis and reduction of unnecessary operating, more can be done by combating criminal abortions and by recognizing that therapeutic abortions, when sensibly indicated and properly performed, may actually reduce both fetal and maternal mortality.

The Management of Colitis. By J. Arnold Bargen, M.D., F.A.C.P., Assistant Professor of Medicine, The Mayo Foundation, Rochester, Minn. National Medical Monographs. Edited by Morris Fishbein, M.D. Cloth. Price \$3. Pp. 234 with 94 illustrations. New York: National Medical Book Company, Inc. Doubleday, Doran & Co., Inc. 1935.

This is a short monograph discussing chronic ulcerative colitis, amebiasis, tuberculous colitis and mucous colitis. It is written in excellent style with a clear presentation of many controversial subjects. The material for the book is based on the author's and his colleagues' material gathered at the Mayo Clinic. In the opening chapter the anatomy, embryology and physiology of the colon are discussed with particular reference to their relationship with pathologic developments. The usual methods of study of a patient ill with diseases of the large intestine are mentioned, with emphasis on the important facts to be obtained. The chapter on chronic ulcerative colitis is lengthy, as one would expect from the author, because of his unusual grasp of the subject. He recapitulates his clinical and experimental evidence for a specific diplostreptococcus as an etiologic factor causing this disabling disease. His description of the pathologic features of the disease is excellent. The chapter on amebiasis contains a large number of observations of the author and of others. He suggests the use of emetine, organic arsenicals, such as carbarsone, and chinofon, in addition to other methods of therapeutic approach to this stubborn disease. The chapter on tuberculous colitis is briefly but adequately discussed. The chapter on mucous colitis discusses the etiologic factors concerned in a disease that is not an inflammatory process of the colon. Little has been added to what is already known clinically and therapeutically about this syndrome. The book, as a whole, reflects the ability of the author to handle in a clear and fair fashion a subject that has been controversial for the most part.

Localized Rarefying Conditions of Bone as Exemplified by Legg-Perthes Disease, Osgood-Schlatter's Disease, Kummell's Disease and Related Conditions. By E. S. J. King, M.D., D.Sc., M.S., Honorary Surgeon to Out-Patients, Melbourne Hospital. Cloth. Price \$7.50. Pp. 400 with 70 illustrations. Baltimore: William Wood & Company, 1935.

This monograph comprises the greater part of the material that was submitted for the Jacksonian Prize of the Royal College of Surgeons in 1933 on "The Pathology, Diagnosis and Treatment of Localized Rarefying Changes in Bone as Exemplified by Legg-Perthes' Disease, Osgood-Schlatter's Disease, Kummell's Disease and Pathologically Related Conditions." The material was personally gathered from 160 cases chosen from a larger number encountered in hospital and private practice. The illustrations are taken from these cases. The consideration of the embryology and physiology discussed in section I has been given considerable justifiable prominence. In section II there is some overlapping, particularly with regard to hypotheses and the evidence on which these are based. Much of the evidence presented is roentgenologic and, therefore, special attention has been given to its evaluation. In many of the

current articles unwarranted deductions are drawn from roentgenologic appearances unsupported by pathologic or other observations. In addition to valuable research material on the subject, the author has presented many new points of view. The book is a treat to every one interested in the subject of bone and joint physiology, pathology and surgery. It is a fine book presenting various points of view on many controversial subjects. There is a comprehensive international bibliography.

The Principles and Practice of Medicine Designed for the Use of Practitioners and Students of Medicine. Originally written by the late Sir William Osler, Bt., M.D., F.R.S. Twelfth edition, revised by Thomas McCrae, M.D., Fellow of the Royal College of Physicians, London. Professor of Medicine, Jefferson Medical College, Philadelphia. Cloth. Price \$8.50. Pp. 1196 with 22 illustrations. New York and London: D. Appleton Century Company, Inc. 1935.

Osler's Principles and Practice of Medicine is one of the most widely known of medical books. Since 1892 it has been copyrighted fourteen times by the publishers, three times by Grace Revel Osler, and once by Britton Osler. The present edition has the same outward appearance as the early editions and does not seem to be any larger. The book has been completely reset in a new type which permits more words to the page and is perhaps more easily read. Since Osler's death in 1916, numerous important discoveries have been made and many new methods and products have been put forth. Dr. McCrae, who worked with Osler and who revised this and various previous editions, has kept out of the book things that have little or no permanent value. He has emphasized the necessity of studying the patient as a human being as well as carefully observing all the manifestations of disease that the patient shows. While the aid that often comes from laboratory procedures and instruments is not undervalued, emphasis is placed on the training of clinicians, those physicians who learn everything possible about a patient by the use of their own senses and brains. The growth of medical knowledge has necessitated changes and additions in practically every part of this edition, especially in the discussions of diagnosis and treatment. Some sections are completely new or have been much changed. Among these are the sections on psittacosis, lymphogranuloma inguinale, undulant fever, arachnidism, purified protein derivative, tuberculin hypoglycemia, the digestive disturbances due to food allergy, narcolepsy, cysts of the lungs, aplastic anemia, agranulocytosis and Morquio's disease. The numerous subjects have been conservatively and soundly reviewed. The volume remains therefore a textbook of established knowledge which practitioners and students alike will find of great value.

Experimentelle Untersuchungen über Amöbenruhr. 2. Teil. Die experimentell erzeugten Veränderungen und die Pathogenese der Amöbiasis. Von Prof. Dr. Richard Blüthgen. Beihefte zum Archiv für Schiffs- und Tropenhygiene, Pathologie und Therapie exotischer Krankheiten, Band XXXI, Beiheft 2. Gegründet von C. Mense. Herausgegeben von P. Muhlens, Direktor des Instituts für Schiffs- u. Tropenkrankheiten, Hamburg. Paper. Price 4.80 marks. Pp. 60 with 29 illustrations. Leipzig: Johann Ambrosius Barth, 1935.

Fulminating amebic dysentery was produced in kittens by intrarectal inoculations of bloody mucous material from infected kittens as well as with cultures of *Endamoeba histolytica* grown on Dobell-Laidlaw's medium. Older larger cats were infected less readily. Ulcerations started in the mucous membrane just above the anal sphincter and below the ileocecal valve spread from these points to the entire large bowel. The ulcers extended downward and outward by lysis (to the mucosa, muscularis submucosa and serosa). The mesenteric lymph nodes as well as the blood stream may be invaded, resulting in liver abscesses. Amebic ulceration of the small bowel and stomach have never been observed in kittens. The younger the kittens, the shorter the period of incubation and the more rapid the course of the disease.

Puppies were similarly infected with similar anatomic results but the ulcers were not as deep or as severe, the disease was more chronic and there was a greater tendency to spontaneous recovery. The ulcers began as pin point, discrete hemorrhagic areas and then coalesced. The large bowel above the anal sphincter and below the ileocecal valve seems to be the most susceptible. The ulcerations may remain limited to those two

points, but usually the rest of the large bowel becomes involved. In dogs, amebic ulceration occasionally spreads to the small bowel and stomach. In dogs the submucosa is much more resistant to invasion by *Endamoeba histolytica* than in cats. Invasion of the blood stream and formation of liver abscesses were also more rare. Only once did the author observe amebic liver abscesses in dogs. A dog and a cat were infected by feeding human feces containing many *Endamoeba histolytica* cysts. Infections of rats, guinea-pigs, rabbits and monkeys were not successful. Other workers were successful in inoculating other animals: rats (Lynch), guinea-pigs (Baetjer and Sellards as well as Chatton), rabbits (Huber and Thomson) and monkeys (Dale and Dobell as well as Walker and Sellards). Older heavier animals are quite resistant to infection with *Endamoeba histolytica*. Cats are never infected spontaneously nor do they show cysts, whereas dogs are spontaneously infected from infected dogs as well as in nature by ingesting human feces containing *Endamoeba histolytica* cysts. Dogs infected for long periods developed a true immunity and allergic reactions—skin sensitivity to intracutaneous injections of *Endamoeba histolytica* antigen resulting in a local edematous, hyperemic wheal. Kittens fail to do that because the disease is of short duration.

The Growth of the Surface Area of the Human Body. By Edith Boyd. Assistant Professor Institute of Child Welfare and Department of Anatomy, University of Minnesota. With a foreword by Richard E. Scammon, Distinguished Service Professor in The Graduate Faculty, University of Minnesota. University of Minnesota. The Institute of Child Welfare Monograph Series No. 1. Cloth. Price \$5. Pp. 145 with 50 illustrations. Minneapolis: University of Minnesota Press, 1935.

This monograph is a detailed study of the accuracy of prediction of the surface area from various types of mathematical formulas based on height, weight or other measurements. Including the surface area measurements made by herself and those culled from the literature, Boyd has measurements on 1,114 individuals, including the antepartum group, for comparison of the accuracy of the various prediction formulas.

The biologic and statistical significance of the various possible formulas will be of interest to those intensively working in this field. Boyd has shown that for the antepartum and postpartum period combined the surface area can be adequately represented on the basis of height and weight, by a self-adjusting power equation

$$S = 3.207W^{0.73} - 0.0358106W^{1.13}$$

With this self-adjusting power equation the growth of the surface area is described in a manner similar to that of Scammon in "The Measurement of Man". It is found that growth may be represented by two asymmetrical sigmoid curves joined at about three years with inflection points at birth and puberty. The rates of growth in surface area of the parts of the body follow a developmental sequence from head to foot only during the circumpartum period.

For the postpartum period the surface area can be adequately predicted by the power equation

$$S = k W^a H^b$$

with or without the exponents restricted to exact bidimensionality according to the condition $3a + b = 2$.

Those who use the surface area method of predicting heat production (the basal metabolic rate) will be interested in knowing that the Du Bois height-weight formula is as good as any method but not statistically significantly better than the ones proposed by Meeh, Bardeen, Voit, Brody or Boyd.

Aus der Werkstatt. Von Alfred F. Hoche. Cloth. Price 6 marks. Pp. 299. Munich: J. F. Lehmanns Verlag, 1935.

This is a collection of essays chosen from public addresses delivered by the author, a psychiatrist on numerous occasions since the year 1900. The material covers a wide range of interest from a psychiatric point of view and includes a great variety of subjects. The collection includes discussions on the influence of modern culture on nervous and mental health. Shakespeare and psychiatry, ennui, the shortcomings of the present psychoanalytic movement, the death of the mad king Ludwig, observations on aviation warfare, some humorous notes on currency inflation, and many other topics too numerous to mention in a brief review. This booklet is decidedly not a textbook nor will it greatly interest the general practitioner. It will, however, be a valuable addition to the library of a psychiatrist or to those interested in collateral reading of such subjects.

Principles of Bacteriology. By Arthur A. Eisenberg. A.B. M.D. Director of Laboratories Sydenham Hospital, New York and Mabel F. Huntly, R.N., M.A. Director of Nursing Wesson Memorial Hospital, Springfield, Massachusetts. With annotations and a section on Microbe Variations by F. E. Colten, M.S. Ph.D. Professor of Bacteriology, Vocational School Milwaukee, Wisconsin. Sixth edition. Cloth. Price \$2.75. Pp. 378 with 98 illustrations. St. Louis: C. V. Mosby Company, 1935.

This book was the outcome of the author's lectures to nurses at certain hospitals in Cleveland. He endeavored to supply certain detailed information which the student nurses were unable to find in the textbooks they were then using. The author prepared a book comprising his syllabus of lectures with additions, and written in simple language. This is the sixth edition of his book since 1918. He has made many changes among the most important of which were in the chapter on diseases due to animal parasites. He has rewritten the discussion on the role of the leukocytes in infection, presenting it now from the point of view of Schilling's hemogram. He added a brief section on the reticulo endothelial system, the Neufeld method of sputum typing in pneumonia, brief discussions of psittacosis, brucella, and lymphogranuloma inguinale. There have been many changes also in the chapters dealing with typhoid, tuberculosis, diphtheria, meningitis and gonorrhea. The book has a number of illustrations and a glossary that is an attractive feature in the field for which the book was originally prepared.

Demonstrations of Physical Signs in Clinical Surgery. By Hamilton Bailey, F.R.C.S. Surgeon Royal Northern Hospital, London. Fifth edition. Cloth. Price \$6.50. Pp. 287 with 341 illustrations. Baltimore: William Wood & Company, 1935.

This little volume is richly illustrated, most of the pictures being sharply and accurately explanatory of the points involved. A number of excellent color plates are included. The book is much more ambitious than its name implies, as it is an attempt to cover the field of surgical diagnosis in an abbreviated manner, including not only physical signs but also points in the history and an analysis of the patient's complaints. The author has indeed succeeded in collecting an imposing list of signs in surgical diagnosis. The only adverse criticism is that their value is in many cases not sufficiently discussed. To many of the signs are attached names which in a surprisingly high percentage are not associated with them, at least in the mind of an American surgeon. Furthermore, in a large number of cases the signs go under different names in other parts of the world. In many cases descriptions of signs and symptoms are given which, at least in the opinion of most surgeons today, are of little value. Few surgeons today would admit that adhesions about the appendix can be diagnosed by the referred pain when one presses on the left lower quadrant. Furthermore, it would be a courageous surgeon today who would undertake the diagnosis of chronic appendicitis. While the book may thus tend to give a false sense of the accuracy of diagnostic maneuvers and investigation it represents a long felt need as an epitome of surgical diagnosis. The mere fact that it has passed through so many editions and impressions is ample proof that it has been of service to many.

Die seröse Entzündung. Eine Permeabilitäts Pathologie. Von Dr. Hans Eppinger, o. o. Professor, Vorstand der I. med. Universitätsklinik, Wien. Dr. Hans Kaunitz und Dr. Hans Popper. Mit einem Anhang: Über den molekularen Aufbau der Eiweissstoffe. Von Dr. Hermann Mark, o. o. Professor, Vorstand des I. chem. Universitätslaboratoriums in Wien und Dr. Anton von Wacker, Privatdozent, Assistent des I. chem. Universitätslaboratoriums in Wien. Paper. Price 26 marks. Pp. 298 with 124 illustrations. Vienna: Julius Springer, 1935.

In this book the importance of the extracapillary circulation in the tissues is subjected to an elaborate and interesting consideration. Everywhere in parenchymatous organs between the capillary membranes and the parenchymatous cells is a space in which fluid circulates. Owing to differences in pressure and electrical potential, substances pass back and forth between the blood and the fluids in the tissues. Under abnormal conditions the capillary walls may become so permeable that they permit the plasma of the blood to pass into spaces in tissues, in consequence of which serious physiologic and morphologic disturbances may result. It is this escape of plasma rich in proteins and the consequences that is called "serous inflammation" in

the book a designation which the authors themselves regard as not wholly satisfactory because the primary change is not clearly of inflammatory nature in the accepted sense. The process in question has been spoken of elsewhere as an "albuminuria into the tissues," which also is unsatisfactory because there is no actual passage of urine into the tissues. The different aspects of abnormal accumulation of plasma in tissue spaces are considered in detail. Collapse is presented from the point of view that it may result from a diminution of the blood mass in the circulation due to passage of plasma into the tissues. The role of certain forms of poisoning in "serous inflammation" and collapse, the methods of analysis and treatment of "serous inflammation" in man, and the relations of "serous inflammation" to the lesions in serum disease, beriberi, exophthalmic goiter, pregnancy, cardiac insufficiency, cirrhosis of the liver and other forms of fibrosis are examples of the topics under discussion. The book is a valuable contribution to the study of the abnormal passage of plasma into the tissues.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice Court May Not Disregard Expert Testimony—The plaintiffs sued the defendant a physician, for malpractice. The jury returned a verdict for the plaintiffs, but the trial court, on motion of the defendant, granted a new trial. Thereupon the plaintiffs appealed to the district court of appeal, second district, division 1, California.

In the published report of this case there is no statement of facts involved in the alleged malpractice. The main point raised on appeal was whether or not the trial court abused its discretion in granting a new trial. An expert witness for the plaintiffs testified in the course of the trial, in answer to a hypothetical question, that in his judgment the treatment administered by the defendant was not such as would be commonly adopted and used by reputable physicians generally in the same locality, under the same or similar circumstances. This testimony for the plaintiffs was apparently the only evidence bearing on the negligence of the defendant. The defendant called no expert witness from whose testimony the jury could determine whether or not he used the care and skill required by law. In spite of the latitude permitted trial courts in the matter of granting new trials, said the appellate court, a trial court cannot disregard and ignore uncontradicted evidence which has been accepted as a fact by a jury, when such evidence relates to matters within the knowledge of experts alone. In *William Simpson & Co v Ind Acc Comm*, 74 Calif App 239 240 P 58, the industrial commission rejected the uncontradicted testimony of medical experts on what was the proximate cause of a death. On appeal the court, after citing several decisions, said

The rule to be drawn from these decisions as we understand them appears to be that whenever the subject under consideration is one within the knowledge of experts only and is not within the common knowledge of laymen the expert evidence is conclusive upon the question in issue. It follows that in such cases neither the court nor the jury can disregard such evidence of experts but on the other hand they are bound by such evidence even if it is contradicted by nonexpert witnesses. Under this rule the Commission in the present proceeding, could not reject the evidence of the medical experts when testifying upon any subject peculiarly within their own knowledge.

The defendant contended that the testimony of the expert witness in the present case was not of sufficient substance to sustain a verdict because the witness gave no reasons for his opinion. While it may be true said the court that an expert witness may give reasons for his opinion, he is not required to do so. The facts contained in the hypothetical question propounded to the witness are in themselves reasons for an answer. Furthermore the defendant had the undoubted right to probe for additional reason on cross-examination but he did not exercise that right.

The appellate court was of the opinion that the trial court abused its discretion in granting a new trial and therefore reversed the order to that effect—*Thomason v Hathcock (Calif)*, 46 P (2d) 832.

Malpractice Liability of Original Tort Feasor for Malpractice by Attending Physician—The plaintiff fractured the bone of his right arm by a fall on ice on the outside stairway of the apartment house in which he lived. After filing a suit against the owners of the apartment house, he, in consideration of the payment of \$350, released them from all claims for damages growing out of the accident. Later he sued the physician-defendant in this case, who had treated the fracture, charging malpractice. The physician-defendant denied liability and claimed the benefit of the release that the plaintiff had executed, releasing the owners of the apartment house from liability. The trial court, on motion for judgment, dismissed the case, and the plaintiff appealed to the Supreme Court of Kansas.

As a general rule, said the Supreme Court, the plaintiff, if he exercised due care in the selection of his physician, might have recovered from the owners of the apartment house for the physician's negligence. While there is a division of judicial opinion with respect to this matter, the rule in Kansas has been laid down by the Supreme Court in *Keown v Young*, 129 Kan 463, 283 P 511, in which the court held

When one sustains personal injuries because of the negligence of another and uses due care in selecting a physician to treat his injuries and in following the advice and instructions of the physician throughout the treatment and a poor result is obtained because of the negligence of the physician the law regards the negligence of the one who caused the original injury as the proximate cause of the damages flowing from the negligence of the physician and holds him liable therefor.

When one sustains personal injuries by the negligence of another and settles his claim for damages against such party and executes to him a release and discharge of all suits actions causes of action and claims for injuries and damages which I have or might have arising out of the injuries such release covers and includes a claim for injuries resulting from the negligence of a physician called by the injured party to treat his injuries when there is no claim of a lack of due care in selecting a physician or in following his advice with respect to the treatment.

The trial court followed the rule thus laid down and held that the physician defendant in this case was acquitted of negligence and not liable for the consequences of it. The Supreme Court affirmed the judgment of the trial court—*Paris v Citeden* (Kan) 46 P (2d) 633.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Influence of Heat Regulation on Raynaud's Disease—Pearse studied the influence of body heat regulation in four cases of Raynaud's disease. It was found that, (1) with the hands kept warm cooling the body will cause an attack of vasospasm, (2) warming the body will relieve an attack, (3) warming the body will not prevent an attack if the hands are exposed to cold, and (4) the warming effect of food was inadequate to influence the vasospasm. It is concluded that body heat regulation may have an influence on the vasospasm of Raynaud's disease. This constitutes further evidence that normal forms of stimulation may give rise to an exaggerated vascular response. It suggests that a local abnormality causes this excessive spastic reaction from several diverse motivating factors.

Results of Treatment in Cardiovascular Syphilis—Padget and Moore observed the course of 161 patients with frank forms of cardiovascular syphilis with reference to the effect of antisyphilitic treatment. Fifty-two of the patients had sacular aortic aneurysm. 109 had syphilitic aortic insufficiency. Fifty-three patients died in less than a year and are considered in a separate group as unamenable to the beneficial effects of specific therapy because of the gravity of their disease and its rapid progress. The 108 who survived for more than a year received varying amounts of antisyphilitic treatment. Of these fifty-three are considered in an "inadequate treatment"

group and fifty-five in an "adequate treatment" group. The mean potential period of observation was ten years and eight months. The mortality rate for the poorly treated group was 137 times that of the well treated group in patients with aneurysm, 262 times as great in those with aortic insufficiency, and 202 times as great for the group as a whole. The deaths due to cardiovascular syphilis were 162 times as great in the poorly treated as in the well treated patients with aneurysm, 246 times as great in those with aortic insufficiency, and 206 times as great for the whole group. Seventy patients of the series are dead. The duration of life from onset of symptoms for those dead was 147 times as great in the well treated as in the poorly treated patients for the whole group, 171 times as great in those with aneurysm, and 137 times as great in the patients with aortic insufficiency. The latter figure is not of certain statistical significance. A restudy of Grant's cases of syphilitic aortic insufficiency was made. The mortality rate of his poorly treated group was 135 times that of those well treated, deaths due to cardiac disease were 178 times as frequent in the former as in the latter. No significant difference in the duration of life in his two groups was observed.

Relationship of Heart Block to Coronary Disease—Salcedo-Salgar and White determined the relative incidence of concurrence of auriculoventricular and intraventricular block as shown by electrocardiography, and of angina pectoris and of coronary thrombosis in 4,274 patients with cardiovascular symptoms or signs studied during the last fifteen years. Of these, 1,028 showed clinical evidence of coronary disease. 700 of paroxysmal angina pectoris, 169 of coronary thrombosis and 159 of paroxysmal angina pectoris and coronary thrombosis. Only 88 per cent of 700 patients with angina pectoris uncomplicated by clinical coronary thrombosis showed heart block, either auriculoventricular block (11 per cent) or intraventricular block (73 per cent), or both (14 per cent), and only 131 per cent of 328 cases of coronary thrombosis, with or without angina pectoris, showed heart block, either auriculoventricular block (36 per cent) or intraventricular block (89 per cent) or both (106 per cent). Conversely, of 117 patients with auriculoventricular block, only 94 per cent had angina pectoris without clinical coronary thrombosis and only 119 per cent more had clinical evidence of coronary thrombosis with or without angina pectoris, making a grand total of 213 per cent of cases of auriculoventricular block with clear evidence of coronary disease. Of 181 cases of intraventricular block of all grades, 298 per cent showed angina pectoris without clinical coronary thrombosis and only 93 per cent showed coronary thrombosis with or without angina pectoris. In both groups more than half of the patients had angina pectoris, coronary thrombosis or both. Coronary disease or other pathogenesis responsible for heart block, either auriculoventricular or intraventricular, does not run parallel to gross lesions of the larger arterial stems of the coronary circulation, the obstruction of which produces clinical evidence of coronary disease in the form of myocardial infarction. Intraventricular block was relatively almost as common in cases of angina pectoris without clinical coronary thrombosis as in cases of clinical coronary thrombosis without angina pectoris. The association of auriculoventricular and intraventricular block with coronary disease is frequent enough to be highly significant. The prognosis of either auriculoventricular or intraventricular heart block in older patients is about equally unfavorable whether or not there are associated clinical evidences of coronary disease. The authors conclude that the coronary supply to the auriculoventricular node and bundle and its branches is not necessarily blocked as a result of the lesion (thrombosis or embolism) which blocks the coronary supply to the areas of the heart (anterior apical and posterior basal portions of the left ventricular myocardium) most commonly affected in clinical coronary thrombosis but that such supply may be seriously involved by atherosclerotic or other processes with poor prognosis even when there is no associated angina pectoris or clinical evidence of sudden blockage of the anterior descending branch of the left coronary artery or of the main trunk of the right coronary artery.

Colon Bacillus Vaccine Therapy—During the last four years Mateer and his associates treated with Bacillus coli vaccine more than 1,000 selected cases of chronic functional diarrhea, chronic "toxic vertigo," long standing headaches of the type usually associated with chronic constipation or colon distress, and "unstable" colon. In 125 of these chronic and obstinate cases, vaccine treatment has been instituted in advance of other treatment. In the other subgroups, vaccine therapy has been postponed and subsequently instituted in obstinate cases in which symptoms have persisted after comprehensive therapy. In either instance the results directly traceable to Bacillus coli vaccine therapy can be identified. In thirty cases of chronic functional diarrhea, with an average duration of three and one-half years, Bacillus coli vaccine was administered in advance of any other therapy. There was improvement of the diarrhea in 93½ per cent of this group. There was complete disappearance of the diarrhea in 60 per cent and a marked degree of improvement in another 20 per cent of the group. In 40 per cent of the cases demonstrable improvement was noted after the first or second vaccine injection. In a group of cases of chronic headache, with an average duration of 117 years, and of the type usually associated with chronic constipation or colon distress, 75 per cent were relieved completely. In cases of toxic vertigo and chronic headache of four years' duration, marked or complete relief occurred in 87.5 per cent. In the occasional cases of obstinate spastic constipation, when Bacillus coli vaccine is added to the comprehensive therapy previously instituted there is convincing evidence that the vaccine tends to relax the partially obstructing spasm of the distal colon. In cases of "unstable" colon (non-ulcerative colitis) with obstinate distress or pain that persisted in spite of the usual comprehensive therapy, Bacillus coli vaccine was instituted subsequently. In 70 per cent of this group there was improvement or disappearance of the colon distress. Bacillus coli vaccine constitutes a valuable therapeutic aid if judiciously used in properly selected cases.

Treatment of Carcinoma of Cervix—Bonney has performed Wertheim's operation 483 times for carcinoma of the cervix. The operation has been as drastic as possible, including the removal of most or all of the vagina and the extirpation

of the regional glands. He has classified his cases according to whether the regional glands removed at the operation were or were not carcinomatous. If the patients lost sight of and dying of other disease within five years of the operation are reckoned as having died of recurrence, the five year cure rate is 39 per cent, or, if they are dismissed from the calculation, between 41 and 42 per cent. The regional glands were carcinomatous in 42 per cent of the cases. The patients whose regional glands were growth free ran on the average an operative death risk of 98 per cent, in return for which they gained, depending on which of the two reckonings is employed, a 31 or 55 per cent chance of five year survival, whereas, on the average patients whose regional glands were carcinomatous ran a death risk of 20 per cent to gain a 22 or 23 per cent chance of five year survival. If patients who were lost sight of and dying of other disease are reckoned as having died of carcinoma, the ten year cure rate is 20 per cent, but, if they are dismissed from the calculation it is 33 per cent. Ten year cures are to be regarded as absolute cures. It is not, of course, impossible for recurrence to take place after that lapse of time but the author has not encountered it.

Prevention of Excoriation of Perineum from Sutures—Grad has succeeded in eliminating pain due to excoriation and ulceration of the skin of the perineum and sometimes the anus from being in contact with the ends of sutures. The method consists in preparing a piece of rubber tissue like that from which surgeons' gloves are made. The piece should be 5 inches long and 3 inches wide. In its center, six or seven tiny holes are burned with the point of a pin brought to a red heat. A piece of rubber tubing one-half inch in diameter and 2 inches long, capable of maintaining its round shape, is prepared. On one side of the curve of the rubber tube six or seven tiny holes are burned in a straight line. On the side opposite the holes the tube is split through its entire length in a straight line, so that the tube can be opened up, and when pressure is released the tube closes up again. After the ends of the silver wire have been twisted, the rubber sheet is spread on the perineum and the ends of the wire are pulled through the small openings. The rubber tube is threaded on the silver wires. Over each wire is threaded a perforated lead shot pushed down in the lumen of the tube and made to grasp the wire by flattening the shot. The superfluous portion of the wire is then cut off flush with the perforated shot. The flattened shot holds the suture firmly and lies entirely within the lumen of the rubber tube and the ends of the suture and shot cannot rub against the patient's skin. The rubber sheet, which has first been placed on the perineum, is now tied over the rubber tube with a piece of silk.

Syphilis and Primary Glaucoma—Beckh investigated the incidence of syphilis in a group of 288 white and seventy-seven Negro patients with primary glaucoma, representing all the public ward patients with primary glaucoma admitted to the Wilmer Ophthalmological Institute of the Johns Hopkins Hospital between October 1925 and February 1934. The incidence of syphilis in primary glaucoma has been compared with the incidence of the same disease in cataract. In the white patients the incidence of syphilis was found to be somewhat lower in those with primary glaucoma than in those with cataract and considerably lower than in a series of general medical admissions. In the Negro group the incidence of syphilis was higher in those with primary glaucoma than in those with cataract.

but still lower than in the general medical admissions. A comparison of the average age of the patients at the onset of glaucoma symptoms in the syphilitic and the nonsyphilitic groups showed that the white syphilitic patients were three years older than the nonsyphilitic when their glaucomatous symptoms appeared, while in the Negro patients there was no difference between the two groups. Of the twenty-two patients with primary glaucoma and syphilis, the syphilitic disease process was latent in eighteen. One patient had cardiovascular syphilis verified by necropsy and two had asymptomatic neurosyphilis, while cardiovascular syphilis was tentatively diagnosed in a fourth. A comparison of seventeen syphilitic cases treated by specific therapy and miotics and observed for an average of fourteen months with a series of fifty-two nonsyphilitic cases treated by miotics alone and adequately followed showed a somewhat poorer therapeutic response in the syphilitic group. This study has failed to present any evidence for the view that primary glaucoma is in any way related to syphilis.

Antianemic Treatment in Experimental Polycythemia

—To test the hypothesis whether the function of the liver is to reestablish the normal number of erythrocytes in the blood Marshall produced a sustained polycythemia in rats which were then treated with liver. The polycythemia was produced by

the administration of a milk diet supplemented by salts of cobalt, iron, copper and manganese. Red cell counts of blood obtained by heart puncture revealed a polycythemia of from 10.5 to 13 million cells per cubic millimeter, in contrast to from 7.5 to 8 million for the normal controls. The high erythrocyte count has been promptly lowered to an average of 87 per cent of its initial level within six days by daily injections of 0.25 cc. of a concentrated liver extract. Controls receiving injections of saline or kidney extract maintained a count averaging 115 million. The fall in erythrocytes was only temporary, a return to above the initial level occurring although the liver extract was continued. Administration of desiccated hog stomach brought about a more gradual and less pronounced decrease in erythrocytes, which was maintained throughout the experiment. Feeding of fresh whole liver caused a temporary increase in the already high erythrocyte count, but no lowering occurred. Fresh lean meat produced no change. Certain similarities between cobalt polycythemia in rats and primary polycythemia as it occurs in man are discussed, and some of the theories of direct or indirect hormone control of the erythropoietic tissues are presented. The evidence presented is interpreted by assuming a hormone which originates in the liver and exercises an inhibiting action on hematopoiesis.

Mental Disease Among the Foreign-Born—Malzberg investigated the rates of mental disease among Russians and Poles, in order to contrast the latter with other foreign groups and with native white subjects of native parentage. Exclusive of Italians, these two groups constitute the largest foreign born populations in New York State. There were 481,306 individuals in New York State on April 1, 1930, who were born in Russia, and they constituted 14.8 per cent of the total foreign born population. The Polish group totaled 350,383 on the same date representing 10.7 per cent of all the foreign born in New York State. The study indicates that natives of Russia and Poland had lower rates of mental disease than the other leading foreign born groups and that they even compared not too unfavorably with natives of native parentage. Their rates of mental disease were decidedly lower than those for natives of northwestern Europe. Invidious comparisons of the immigrant populations from a biologic point of view are unjustified. In some eastern European immigrants have lower rates of mental disease than immigrants from northwestern Europe, it is true also that Austrians and Hungarians have rates above the average. If some of the northwestern European populations have moderate rates of mental disease others such as the Irish and the Scandinavians have the highest. Within each of these broad aggregates of population there evidently are some groups

with high rates and others with low rates. It appears pertinent therefore to concentrate on the causes of variation within each group rather than to dispute endlessly over hypothetical racial causes of mental disease.

Effect of Alcohol in Catatonic Syndromes—Kantorovich and Constantinovich observed that alcohol often interrupts the course of catatonic stupor, producing a temporary, and sometimes lasting, cessation of mutism, torpor and negativism. Under such circumstances it often becomes possible to gain access to the content of the patient's psychotic trend as well as to facts of case history. Should further experience with alcohol in catatonic and hebephrenic cases yield similar results, the conclusion would be justified that a safe and simple procedure has become available as both a therapeutic and a diagnostic aid in the psychiatric clinic.

Diabetes—Beck and his co-workers point out that calcification of the arteries of the lower extremities (demonstrated roentgenologically), which is so common particularly in uncontrolled diabetes among older persons is essentially absent in patients with early diabetes and obese people some of whom are potentially diabetic. No evidence was found to show that hypertension or retinal arteriosclerosis could be correlated with the obese patients' ability to use dextrose. The incidence of hypertension appears to be higher in older diabetic patients. This is essentially related to obesity and not to diabetes. Obesity, hypertension and diabetes appear to be unquestionably influenced by a hereditary factor. All three may be found together or in various combinations. It appears that obesity increases the likelihood of both diabetes and hypertension but it is less certain that the presence of hypertension contributes to the probability of diabetes, since the incidence of hypertension is about the same in the nondiabetic obese person as in the obese diabetic person. With the mechanism of the production of diabetes so incompletely understood its pathologic anatomy so variable and the possibility of extrapancreatic influences so definite, it is not surprising that many should regard the inception of diabetes as a functional disturbance. It may be more logical to think of it as a different reaction at various ages. It is conceivable also that the presence of vascular degenerative changes in the pancreas may be a factor in the production of diabetes but it seems unlikely that it is the sole cause. If it were so, diabetes in the aged and in patients with high grade hypertension should be more common unless an elective vascular disease of the pancreas exists. Also atherosclerosis in older people is more common in men than in women. Diabetes however in the same age group is more common in women.

Helium in Treatment of Asthma—Barach states that a mixture of 80 per cent helium and 20 per cent oxygen has one third the weight of a comparable volume of air. It was assumed that a relatively light respirable gas could be breathed with less effort in clinical conditions in which difficulty in ventilating the lungs was present. In four patients with severe

asthma, inhalation of helium-oxygen mixtures appeared to be of considerable benefit. When continuous asthma was present subjective and objective relief were obtained. In three cases a grave asthmatic condition and refractoriness to epinephrine were removed by inhalation of helium-oxygen mixtures. The acute attack of asthma was not aborted, and the relief obtained by inhalation of various mixtures of helium and oxygen was not sufficient to replace epinephrine when this drug was effective. The special value of helium-oxygen mixtures is in the treatment of asthma persisting after epinephrine and in status asthmaticus. Graphic records of the quantitative and qualitative changes in pulmonary ventilation revealed the following consequences of inhalation of helium-oxygen mixtures in a patient with continuous asthma: (1) decrease in pulmonary ventilation, (2) decrease in pulmonary pressure, (3) relative and absolute diminution in the length of expiration and (4) increased rest period between respiratory cycles. The decreased pulmonary pressure and the swifter flow of gas during the early phase of expiration would appear to lessen the likelihood of alveolar distention and emphysema in patients who have much continuous asthma. Severe obstructive dyspnea in two infants, one with laryngeal and the other with tracheal obstruction, was relieved by inhalation of helium-oxygen mixtures. In one of these cases, the infant was comfortable in a helium-oxygen tent for eight days, but the congenital nature of the obstruction was such as to require tracheotomy ultimately. In conditions of laryngeal or tracheal obstruction in which there is a possibility of the obstruction clearing up, the inhalation of helium-oxygen atmospheres may be useful by providing relief from a severe form of air hunger and its consequent fatigue of the respiratory musculature. The relief of dyspnea in patients suffering from various types of respiratory obstruction during the inhalation of helium-oxygen mixtures made evident the importance of an accustomed volume flow of gas to and from the lungs. This special equilibrium, i.e., the maintenance of a certain required pulmonary air flow, is regulated by proprioceptive reflexes from the lungs and the respiratory musculature. Disturbance in this equilibrium is the primary cause of the sensation of air hunger in this type of dyspnea, anoxemia may occur in severe cases as a secondary complicating factor.

Symptomatic Psychoses in Pernicious Anemia—Three cases of classic Addisonian pernicious anemia observed by Preu and Geiger are reported in which the psychoses seem clearly to bear a symptomatic relationship to the deficiency disease. The patients showed the fundamental symptoms of an organic psychosis. The first patient seemed confused on admission, and disorientation was observed on several occasions before improvement in the mental picture began. She was very easily fatigued, her attention was poor, and her intelligence was dull, but the authors did not feel that these features accounted for the disorientation and confusion. Memory seemed impaired at first but it gradually improved, as did the other organic mental symptoms under specific treatment. Although the second patient was clearly oriented on admission, disorientation for time and place was observed two days later as well as on several other occasions. Brief episodes of nocturnal confusion were observed which they believed likewise indicated clouding of consciousness. Memory seemed poor but showed no striking change and was difficult to evaluate because of the limited intelligence of the patient. The defects in orientation and the episodic confusion improved under treatment. The third patient was found to be definitely disoriented for time on a number of occasions, and recent memory defects were demonstrated repeatedly at times when her attention and cooperation were satisfactory. No improvement in the symptoms occurred during two weeks of specific treatment after which death occurred from a pulmonary complication. The opinion of the psychiatric staff was in favor of a diagnosis of symptomatic psychosis in all three cases on the basis of the organic symptoms discussed. The character and severity of the mental disturbances bore no consistent relationship either to the degree of anemia or to the extent of the neurologic manifestations. While this may appear implausible it seems to the authors fully as admissible as the well established observation that neurologic involvement varies independently of the state of the blood, subacute combined sclerosis sometimes appearing long before the actual develop-

ment of anemia Goldhamer and others have observed that cerebral manifestations may occur either alone or in association with cord disturbance, that they may be present with or without evidence of anemia, and that they may present themselves as the earliest and only manifestations of pernicious anemia

Vitamin A Deficiency and Congenital Atresia of Bile Ducts—Altschule discusses the postmortem study of eleven infants with congenital atresia of the bile ducts. All had received diets adequate in vitamin A and none presented clinical evidence of xerosis or keratomalacia during life. Microscopic changes diagnostic of vitamin A deficiency, as defined by Wolbach and Howe, were observed in six, and the clinical histories and the necropsies in these six cases are presented. In each of these cases the family history was irrelevant. The deficiency apparently occurs as a result of failure of absorption of vitamin A from the gastrointestinal tract due to the absence of bile. There is evidence indicating that the parenteral administration of vitamin A is effective in patients in whom vitamin A deficiency develops as a result of severe obstructive jaundice. The oral administration of the vitamin together with bile salts also is possibly of value.

Desiccation of Hemorrhoids—In his desiccation method for hemorrhoids Graham uses about 2 ounces (60 cc) of a 1 per cent solution of procaine hydrochloride to which about 4 minims (0.3 cc) of epinephrine has been added. A 20 cc syringe with a 1½ inch, 22 gage needle is used for its injection. The skin is pierced by the hypodermic needle at the anterior anal margin and is carried up to and into the sphincter ani muscles, injection of the fluid being made as the needle enters. The needle is then almost withdrawn and its direction changed so that it is pushed laterally and posteriorly on each side of the anal margin. The needle is then completely withdrawn and a similar injection made at the posterior anal margin. In a very few minutes the sphincter muscles relax around the surgeon's finger and the external and semienternal piles can be turned out easily and a good view of them obtained. They are now ready to be desiccated. An diathermy machine with a good Oudin coil attached is suitable. Ordinary sewing needles from 2 to 4 inches long may be used. The current is turned on and the spark gap is adjusted so that the current will be of a strength to throw a spark about one eighth inch in length. The needle is inserted into the base of the pile about one eighth inch from its margin and is held steady until an area of desiccation appears in the form of a dirty gray color around the needle. In external and semienternal piles it suffices to desiccate around their base leaving them to slough off gradually. As much of the internal piles as can be reached should be desiccated through a speculum. A hemorrhoidal suppository is inserted and the operation is completed. Postoperatively a tablet containing an antipruritic and a halt grain

(0.03 Gm) of codeine is prescribed for pain. Liquid petrolatum emulsified with agar-agar is ordered as a combination best preventing seepage from the intestine and promoting a gentle and soft intestinal motion least irritating to the inflamed parts. After the initial contraction of the piles there follows a reaction that causes swelling of the parts, and with large external piles the patient may be unable to replace them for about two days. If these become painful hot fomentos or sitting in a hot bath generally give relief. By that time contraction starts to take place, the swelling goes down rapidly and the piles can be replaced with ease. The patient is not hospitalized and remains at home for only three days preferably in bed.

Clinical Use of Human Placental Extract—Goldberg and Lissner believe that they gave the alcohol soluble ether insoluble complex present in acetone extracts of human placenta (emmenin Collip) an adequate trial by employing it in 100 instances of various menstrual disorders, occurring in sixty-six women. It has proved helpful in restoring menstruation if periods have been absent less than a year. It is probably useless in amenorrhea of longer duration. In eight of nine cases of oligomenorrhea the menstrual interval was more nearly regularized. The same result was accomplished in seven patients whose menstrual interval was utterly irregular, sometimes too soon other times too late. Polymenorrhea was unaffected in the only three cases in which the preparation was used. Hypomenorrhea was definitely improved in nine of twelve cases. Menopausal symptoms and cyclic menstrual headaches were relieved in a fair majority of cases. In two of four cases of sterility, pregnancy occurred under its therapy. More than 60 per cent of forty subjects with severe dysmenorrhea were remarkably relieved. Psychic factors were rigidly excluded. This constitutes its most significant clinical usefulness.

Laurence-Moon-Biedl Syndrome—Molitch and his associates describe three brothers affected to a different degree with a hereditary cerebral defect. All three had polydactylism, mental deficiency, pituitary dysfunction and some visual defect. The oldest brother (aged 16) has also retinitis pigmentosa while the next oldest (aged 11) has a severe degree of myopia with a tessellated appearance of the retina. The youngest brother (aged 8 at death) had a mild visual defect with strabismus. It is concluded that all cases occurring in the same family and showing all or almost all the cardinal symptoms of the Laurence-Moon-Biedl syndrome should be so categorized. Isolated cases without other siblings being affected and not showing all the cardinal symptoms should not be included in the syndrome. Reilly and Lissner in their survey and summary of the literature concluded that the syndrome consists of six cardinal symptoms: obesity, mental deficiency, genital atrophy, polydactylism, retinitis pigmentosa and familial occurrence.

Compensatory Changes Following Pneumonectomy—
 Rienhoff and his associates found that the compensatory
 changes in the remaining lung following total pneumonectomy
 in dogs consist of simple dilatation of the respiratory lobules
 or the definitive respiratory units made up of the respiratory
 bronchiole, the alveolar ducts, the atria, the alveolar sacs and
 the alveoles. This dilatation comes in response to increased
 physiologic demands and is of a compensatory nature. It is
 not an emphysema and there is no interruption or diminution
 of the elastic tissue or fusion of the alveoles to suggest patho-
 logic change in the parenchyma of the lung. There is no
 increase in the number of the bronchial trees or in their pat-
 tern, and apparently the blood vascular system, except for a
 possible dilatation, is unaffected. No evidence of true hyper-
 plasia or hypertrophy was found. The lack of uniformity of
 dilatation of the alveoles in any one section was found to be
 due to the fact that the serial sections were cut through the
 alveoles at different levels of the block of tissue. The maximal
 diameter of different alveoles is, of course, situated in different
 planes.

Metabolism During Reproductive Cycle—Hunscher and
 her associates extended a case study over a period of eight
 years of child bearing and child rearing in a woman when she
 and her children were known to enjoy buoant health. Unin-
 terrupted nitrogen metabolic responses during the last half of
 fetal development and the physiologic preparation of the mater-
 nal body for lactation and the extension of these observations
 into parturition puerperium and eight weeks of lactation showed
 where some of the stresses and strains of maternity lay. The

results confirm previous considerations derived from intermit-
 tent balances in two former reproductive cycles in the same
 woman. During the last 145 days in gestation there was an
 average net storage of 31 Gm and a maternal retention of
 26 Gm of nitrogen daily, resulting in a total observed accu-
 mulation of 446 Gm at term. On the day of delivery the
 chemically determined maternal loss in blood, placenta, amniotic
 fluid and vomitus amounted to 46, 20.1, 0.08 and 0.24 Gm of
 nitrogen, respectively, the total loss from the body beyond the
 food consumed amounted to 546 Gm of nitrogen in addition
 to that contained in the fetus. The nine daily balances during
 the lying-in period showed an average daily loss of 5 Gm of
 nitrogen. From the tenth to the fifty-third day of lactation
 there was an average daily loss of 0.87 Gm of nitrogen. By
 the fifty-third day of milk flow the gestatory reserve nitrogen
 had been reduced by delivery, puerperium and lactation losses
 of 54.6, 44.6 and 38.3, respectively, leaving a total of 310 Gm
 of nitrogen stored only in the last half of pregnancy. When
 the approximate fetal content of 586 Gm of nitrogen is
 deducted from the final maternal reserve, the accountable losses
 of the reproductive cycle by the fifty-third day of lactation had
 left a maternal reserve of 250 Gm of nitrogen for future
 dissipation or enrichment of the maternal body at termination
 of the reproductive cycle.

Mushroom Protein Is Incomplete—Quackenbush and his
 co-workers studied the nutritive properties of the mushroom
Agaricus campestris by feeding the mushrooms to albino rats.
 Diets that contained mushrooms were consumed in subnormal
 quantities, and consequently growth was subnormal. Excep-
 tions to this general result were observed when mushrooms
 were fed to animals that were depleted in vitamin B or G.
 Mushrooms were found to be a relatively good source of vita-
 mins B and G. Levels of 10 and 5 per cent of the diet on a
 dry weight basis supplied sufficient vitamins B and G, respec-
 tively, to support satisfactory growth. The data indicate that
 a diet containing 10 per cent of mushrooms as the only source
 of vitamin B is deficient in some factor other than vitamin B
 or G. Mushroom protein is incomplete.

Antirachitic Activity of Vitamin D Milks—The results
 of the experiments of Haman and Steenbock show that for the
 chick and per unit of vitamin D 1 irradiated milk cod liver
 oil and irradiated cholesterol are of approximately the same
 order of effectiveness. 2 Yeast milk is approximately one
 tenth as effective as irradiated milk. This difference was
 confined to the respective butter fat fractions and was not
 influenced by the skimmed milk fraction. 3 The constituents
 of milk as a vehicle for vitamin D do not influence its effec-
 tiveness. 4 The experiments give no support to the possibility
 that the baby chick could be used to greater effectiveness than
 the rat for ascertaining the degree of antirachitic effectiveness
 of different vitamins D for the human being.

Congenital Scurvy—Jackson and Park discuss observa-
 tions on a baby of 20 days in whom the lesions in the bones
 were exactly like those present in the infant suffering from
 acquired scurvy. Every histologic manifestation in the skeleton
 found in acquired scurvy was present in this congenital case.
 lattice formation, fracture of the lattice with fibrinogen and
 collagen leakage, cessation of osteoblastic activity, destructive

processes in the sublattice region migration of the marrow cells from the ends of the growing bones with exposure of the embryonal-like connective tissue, internal and subperiosteal hemorrhage, and thinning and atrophy of the cortex in the lattice region with fracture. The authors state that the photomicrographs of the lesions in acquired scurvy compared with those of their case are so similar as to be interchangeable. There cannot be the slightest doubt, therefore, that the case reported is one of congenital scurvy. The severity of the lesion at the various cartilage shaft junctions corresponded with the rate of growth. If the rate of growth was slow enough at the end of a bone the signs of the disease did not appear. The case indicates that in scurvy the lattice must be so fragile that it cracks and breaks from the strain of ordinary movement or support of the arms and legs. Fractures of the lattice in scurvy are far more general than is popularly thought and are probably present in every case in which the disease has progressed far enough to be recognizable roentgenologically. They must precede epiphyseal separation for some time.

Scarlet Fever Immunization by Inunction—Ripps tested 564 children ranging in age from 1 to 16 years, 213 of whom were Dick positive. Most of these children were residents of four orphan institutions; the remainder were obtained from private practice and the hospital clinic. Dick toxin, prepared from the N Y 5 (Docher strain) of a potency of 24,000 skin test doses was mixed with 2 cc of plain rose water ointment or anhydrous wool fat. All the Dick positive children were given five massages over the entire back at intervals of one week. Preceding the rubs, the backs were cleansed with alcohol. For the first two rubbings, inunctions containing approximately 24,000 skin test doses were used and 28,000 skin test doses for each of the last three rubs. There were no general systemic reactions. About 20 per cent of the children showed a mild dermatitis over the parts rubbed after the first application, which was often associated with itching. With the succeeding massages, the skin reactions were less frequent. At no time was the dermatitis distressing. The eruption usually disappeared within two days. A total of 112 Dick-positive children completed the course of massages and were retested at various intervals. Of seventy-five children who received the rose water ointment inunction 66 per cent were immunized. Of thirty-seven children who received the anhydrous wool fat inunction 30 per cent were immunized. Twenty-one children ranging in age from 1 to 3½ years were given rose water ointment inunctions containing 50,000 and 75,000 skin test doses for the first and second rubbings, and 100,000 for each of the remaining three rubs. Four of these were rendered Dick negative. Nine children, whose ages ranged from 4 to 10 years were given five rubbings at five-day intervals, the skin test doses being 50,000 and 100,000 for the first and second and 150,000 for the remaining three. Only one was immunized. Thirty-two children, who did not become negative after six months, were given three additional rubs with 50,000, 100,000 and 150,000 skin test doses. Only two of these had become negative when tested one year later.

Third Generation Syphilis—Rosenbaum and Faulkner believe that the two complete family histories which they give fulfil essentially the requirements for proving the existence of third generation syphilis. The grandmothers in both instances are still alive. In one a history of antisyphilitic treatment was obtained for her and her husband in 1910. In the case of the other there was no knowledge of syphilis until the authors' Wassermann and Kahn examinations of the blood were returned positive in 1933. Both the grandfathers are now dead. The causes of death cannot be ascertained, although both of them died suddenly at comparatively early ages. From these two unions which were in no way consanguineous, children and grandchildren have come under observation. All members of the second and third generations have been examined and male and female are affected. One member in each second generation escaped the infection. This member is flanked on either side by a brother or sister who has positive blood Wassermann and Kahn tests. The girls' two in each family have married and borne children. The husband in each case has remained negative clinically and serologically and none of them gave a history of syphilis. None of the women gave any history or evidence of having required syphilis yet each gave strong positive

Wassermann and Kahn reactions. One of these women, however, gave unmistakable evidence of congenital syphilis. She has definite pegging and notching of the upper middle incisors. Likewise her younger brother who is now 16 years of age, shows the same congenital stigma and has strongly positive Wassermann and Kahn reactions. Evidence of congenital syphilis in physical examinations has not been found in the four other members of the second generation. They have, however, positive Wassermann and Kahn reactions. One or more children from each of the four women of the second generation are under observation because of physical or serologic evidence of congenital syphilis. All the children of the third generation in one family showed this evidence early with physical stigmas and positive Wassermann and Kahn reactions. The children of the third generation in the other family show no marked stigmas.

Effect of Dinitrophenol on Blood Velocity—Wohl and Ettelson determined the blood velocity in thirty-three obese patients. The basal metabolic rate of these patients varied from minus 25 per cent to plus 16 per cent, the average being minus 65 per cent. The average arm to tongue circulation time was 13.3 seconds. Obesity alone had no appreciable effect on the circulation time if it is assumed that the normal limits are between ten and fifteen seconds. In fourteen cases, dinitrophenol was administered orally in doses of 300 mg a day for periods varying from one to five weeks. In seven cases acceleration of the blood flow occurred averaging 3.3 seconds per patient, while in the remaining seven cases no significant change in the blood velocity could be demonstrated. In no instance was there a slowing of blood flow while dinitrophenol was administered. In the majority of the fourteen patients receiving dinitrophenol there were weekly losses of weight even though no attempts at restriction of diet and fluid intake were made. In other instances, however, the total loss of weight over a period of several weeks was no greater than that which has occurred on high protein, subcaloric diets without medication of any kind and in one patient a gain of 5½ pounds (2.5 Kg) over a period of two weeks was observed, during which time the basal metabolism was at a level of plus 60 per cent. This patient consumed large quantities of fluids in an attempt to relieve epigastric burning sensations which the drug produced. In two cases in which several metabolism readings were made a drop was seen after the primary elevations caused by the drug. One patient, after four weeks of dinitrophenol, had a basal metabolic rate of plus 40 per cent. The drug was continued for two more weeks, at the end of which time the rate was plus 20 per cent. The course of the other patient was quite similar. The author cannot offer a satisfactory explanation at present for this fall in metabolism. Skin rashes occurred in six of the group, the incidence being higher than that reported by Tainter, Stockton and Cutting. In one patient the drug produced so many untoward symptoms that it was necessary to discontinue its use before blood velocity tests could be completed.

Surgical Procedure in Polycystic Kidneys—Although cases of unilateral polycystic kidneys are reported, Goldstein believes that the condition is always bilateral, either at the time of operation or subsequently. In view of the fact that medical regulation of the uncomplicated polycystic degeneration of the kidneys has not resulted in any considerable benefit to the patient, he feels that radical methods are indicated in many instances. If early surgery was performed in some of these cases before complications arise, life might be prolonged and much suffering avoided. When the abdominal route is employed, a pararectus high Gibson incision is made down to the peritoneum. The peritoneum is pushed medially and the kidney with its fatty layers is exposed. It is then freed laterally on each side. The true capsule is incised lengthwise, some of the cysts being opened. Numerous large cysts are then opened and the walls of many are excised. As many as possible of the cysts are drained. After this procedure the kidney cortex is split from one pole to the other. The incision should not go through the calices if possible, and certainly not into the pelvis. With the kidney split, more cysts are drained with the needle and syringe. The medial half of the longitudinal portion of the kidney is then sutured to all the layers of tissue above and medial to it, the peritoneum being pushed downward and inward. The other half of the longitudinal split portion is treated likewise. The wound is closed with interrupted plain catgut sutures. At the end of the operation the kidney is well immobilized and the split cortical portion is exposed. The split halves are approximated to the skin edges. Medially the peritoneum is underneath the muscular structure of the abdomen as well as being in close apposition to the hilus. Laterally the same situation exists, except that the kidney is not in apposition to the peritoneum. This leaves the organ free so that the cysts may be punctured with a needle and syringe under visualization at will, after healing. When the lumbar route is employed the same steps are carried out except that the immobilization is in the lumbar rather than the abdominal region. The entire length of the incision in the kidney in both instances is left open and sutured to the skin. Wet gauze is applied to the wound, which is kept open as long as possible. Granulation takes place in about four weeks after which the wound is permitted to heal over. This takes between six and ten weeks. A large scar forms over the wound.

Research on Prostatic Hypertrophy—Lower and his co-workers summarize the pertinent facts that have formed the basis for a theory as to the cause of benign prostatic hypertrophy

and constitute the background for the rationale of the therapy that they employed in a group of clinical cases. During the course of these and other experiments, evidence was produced that indicated the probability of the existence of a testicular hormone (which they call "inhibin"), which would depress the gonadotropic activity of the pituitary gland. Its clinical use was begun about ten months ago and forty patients with prostatic hypertrophy were treated with it. The ages of the patients ranged from 51 to 80 years. All cases presented the typical symptoms of prostatic obstruction, such as hesitancy, slowing of the urinary stream, nocturia and frequency. The majority of cases were hospitalized for preliminary investigation. After critical analysis of the forty patients, the authors consider twenty-six (65 per cent) markedly improved to the point at which they are virtually symptom free. Eight patients with complete retention now enjoy urinary comfort, five without any residual urine, two with only 30 cc and one with 50 cc residual urine. In all the other cases except one the residual urine has diminished or disappeared, and in that one only 30 cc was present at the beginning of treatment. Nocturia has been the symptom from which these patients showed the most consistent improvement though each patient made the unqualified statement that there was greater ease in voiding and a sense of complete emptying of the bladder. In many patients the kidney function improved and elevated blood ureas returned to a normal level. Many patients expressed a feeling of general well being and greater endurance. No improvement could be noted in fourteen patients. A careful analysis of the unimproved cases yields no consistent factor to explain their failure to respond. In general the symptoms were of longer duration, the average duration of symptoms in this group being 5.5 years as against 3.1 years in the improved cases. The incidence of urinary infection was relatively much higher. Five of the fourteen unimproved patients had large, atonic chronically overdistended bladders. A small sclerotic type of gland appeared to account for the failure in two other cases. From 10 to 20 per cent of enlarged prostates may be expected not to be benign enlargements, and this may account for some of the failures.

Carcinoma of Vas Deferens—Thompson and Pilcher point out that carcinoma apparently never develops as a primary tumor of the vas deferens. On first thought it would seem possible that carcinoma might frequently occur in the vas deferens as an extension of the malignant condition in the prostate gland, seminal vesicles or testes. The rarity of such extension, however, is attested by the fact that a thorough search of the literature disclosed only the references to Young, who found in a few cases, involvement of a portion of the vas deferens adjacent to the prostate gland. The secondary extension of prostatic carcinoma along the entire length of the vas deferens as far as the testes has never been described. Such a case, in which the process could be palpated within the scrotum is reported.

Sinus Thrombosis—Wolf accounts for the result in his ten consecutive cases of sinus thrombosis with no mortality as due in part to the following considerations: 1 The patients were in good general condition and were seen early in the course of the disease. 2 In all instances the involvement was unilateral thus pointing definitely to the side affected. 3 The splendid cooperation on the part of the laboratory, the house staff and the nursing staff was a factor of no mean importance in securing the favorable results. 4 In none of these cases was a mastoidectomy performed simultaneously with the obliteration of the lateral sinus and the ligation of the jugular vein. Thus prolonged operation with resultant shock to the patient and excessive loss of blood was avoided.

- Jaundice and Ascites with Recovery Report of Case J R Cavanagh Washington—p 322
- Congenital Arteriovenous Fistula Report of Case S Dessoff and W H Angvine Washington—p 324

Meningococcemia—During the outbreak of meningitis occurring in Washington during the past winter and spring months Conklin encountered two cases that illustrate the overwhelming blood infection that sometimes occurs with early demise and the type with prolonged evidence of blood infection with later frank symptoms of meningitis followed by recovery. The first patient, when first seen, was evidently suffering from an acute infectious disease with hemorrhagic manifestations. Everything from typhus to drug dermatitis was suggested by those who saw him. Cerebrospinal meningitis was suggested despite the absence of neurologic clinical evidence. The blood culture and spinal fluid smears and cultures made the latter diagnosis certain. The other patient represents the type showing meningococcemia for days before meningitis develops. Although the organism was not recovered in this case, the resulting situation and the initial classic picture make the presence of meningococcus in the blood stream highly evident. The symptom grouping of irregular temperature, joint pains, chills and sweats and petechiae, all common factors in a number of infections of the blood stream, should call for frequent blood cultures with the idea in mind of the possibility of a meningococcal infection. When the patient was discharged from the hospital he was thoroughly clear mentally, able to stand alone and, except for nocturnal enuresis, in remarkably good condition. He had had thirty-one spinal taps, a total of 395 cc of antimeningococcus serum had been administered, and five blood transfusions, frequent intravenous injections of dextrose and two of magnesium sulfate had been given.

Chronic Pyelonephritis in Children—Caulk states that the most common cause of chronic pyelitis in infants and children is obstruction at the internal orifice of the bladder resulting from congenital valves or contractures. Regurgitation of the vesical contents into the ureters and kidney pelvis was present in 46 per cent of his twenty-six cases. One half of these occurred in the presence of a high, the remaining half with small, residual urine. Operations were performed on sixteen of these children, fourteen cauterized punch and two suprapubic, six were for valves, one for valve and bar, seven for contractures of the vesical neck and two for lobules. The child's punch was used in nine instances and the baby punch in five. Thirteen of the operations have given perfect results. Two were decidedly improved but not completely satisfactory. The parents refused to allow further surgical procedures. One case in which there was pronounced spina bifida with a very thin delicate valve, was not improved. The removal of the valve gave no benefit. The results following the removal of the obstruction through the urethra in children by means of the punch have been the most gratifying that the author has had in surgery. The end results have been satisfactory, invalid children have been restored to excellent health with practically no complications or untoward effects and with no mortality. This series of cases of obstruction of the neck of the bladder treated by transurethral removal is as far as he can determine, the only one so far reported. He urges the profession to suspect such mechanical causes for the majority of persistent or

recurrent cases of pyelitis in infants and children and to seek early investigation for such cases so that prompt corrective measures may be applied.

- Factors in the Management of Constipation T E Clow Wolfboro N H—p 1187

Progressive Idiopathic Pulmonary Fibrosis—Hampton discusses cases of chronic pulmonary disease about which little is known and which are often misinterpreted as pulmonary tuberculosis. Various other clinical diagnoses are made, such as asthma, bronchiectasis, heart disease, malignant conditions and pneumoconiosis. While he speaks only of cases in which postmortem examinations have been made, even a complete pathologic examination does not allow accurate classification. Most of the postmortem observations are similar and are characterized by diffuse interstitial fibrosis, distortion and dilatation of the bronchi, diffuse emphysema and, in the advanced cases, emphysematous blebs. The pulmonary changes seen at the routine roentgen examination, which are due to idiopathic fibrosis, are quite similar to those seen associated with tuberculosis. The chief difference is that usually tuberculosis is more localized and less likely to involve the entire lung fields. Fibrosis, however, may occur locally in both infraclavicular regions and, as in the case of pneumoconiosis, the upper lobes are quite commonly involved. Emphysematous blebs add to the confusion of the roentgen picture, in that they are often quite similar to the cavitation of tuberculosis. Pleural thickening and even pleural effusion are also common. The thin walled dilated bronchi and confluent emphysematous alveoli that occur often produce a diffuse honeycombed appearance on the roentgenogram. This picture is rarely seen in tuberculosis, and there are certain other helpful differential points in the roentgen examination which are obtained only by fluoroscopy and oblique and lateral roentgenograms.

- Weather Condition and Blood Plasma Volume J H Black Dallas—p 516

Puerperal Eclampsia—King considers the prophylaxis of eclampsia under three heads: adequate antepartum care, prompt and adequate treatment of the toxemia and induction of labor in patients not responding satisfactorily to treatment. Eclampsia occurs in about 1 per cent of the cases coming to a maternity hospital and in from 0.1 to 0.2 per cent of patients in private practice. It is more frequently found in primiparas. The maternal mortality rate varies from 10 to 20 per cent, while the fetal rate is from 30 to 50 per cent. Once eclampsia has developed, a conservative plan of treatment should be adopted and carefully followed. In an occasional case cesarean section under local or spinal analgesia, may be performed. The summaries of the various conservative methods for the treatment of eclampsia given include the Stroganoff, Dublin (Rotunda), Schwarz-Dorsett, sodium amytal, Lazard and Miller and Martinez procedures.

Leukocytic Variations in Radium Workers—Goodfellow performed systematic blood counts at intervals of from two to four weeks on thirty-two workers in radium and x-rays. The periods of observation varied from six months to three years according to the duration of each individual's appointment. It has been found that there is only one sign of early overexposure that is common to all workers. This is a leukopenia due to a reduction in the number of circulating neutrophils. There is evidence that different individuals vary in their susceptibility to the effects of irradiation, and those who are more sensitive exhibit an absolute lymphocytosis with an absolute neutropenia as a first sign of overexposure. Others, who are less sensitive, exhibit a lymphocytopenia with a monocytosis under similar circumstances. Eosinophilia has frequently been seen as a result of overexposure, and abnormal or embryonic leukocytes have occasionally been seen in the blood of certain workers. Vacations of less than four weeks do not appear to be of value in restoring the leukocyte count of an overexposed worker to a normal level. The value of the information obtained by these routine blood counts has been greatly enhanced by periodic clinical examination of these subjects.

Aortic Stenosis—Gibbs studied and analyzed the clinical records and morbid anatomy of twenty-seven patients. Twenty-six have died and the notes of the necropsies have been studied in fifteen of these the hearts had been preserved and were available for further examination. Of the two causes of aortic stenosis most likely to be encountered, rheumatism predominates in patients less than 50 years of age and arteriosclerosis in patients more than 50. Syphilis is practically never a cause, and congenital defects or infantile endocarditis only rarely. In the rheumatic group aortic stenosis is as common in women as in men, but in the arteriosclerotic group it is almost confined to men. Calcification of the valve cusps essential to the production of aortic stenosis in arteriosclerotic patients, may be a contributory factor in aortic stenosis of rheumatic origin though more commonly in men than in women owing to secondary arteriosclerotic changes. While calcification may result from diminished blood supply to the valve ring, as a result of

inflammatory or degenerative changes in the nutrient vessels, healed valvulitis and excessive strain also produce it, but at the free margin of the cusps instead of in the fibrous ring. The symptoms of aortic stenosis are in no way characteristic and the classic signs are often modified and obscured by the presence of other valvular lesions and by failing compensation. While the majority of patients suffering from rheumatic aortic stenosis in combination with mitral disease die at comparatively early ages (less than 50), having been invalids for a number of years, those patients suffering from arteriosclerotic aortic stenosis may live to a reasonable old age if careful to avoid any excessive cardiac strain.

Pathology of Some Uncommon Enlargements of Lymph Nodes—Goyle and his associates discuss five cases of universal and local enlargement of lymph nodes. Histologically, the main features of the first case are hyperplasia of the bone marrow and the presence in the viscera of aggregations of small lymphocytes, many of which, however, lack the typical nuclear structure of the ordinary small lymphocytes. The hyperplasia has been regarded as lymphoblastic. The total number of leukocytes in the blood stream was not increased and the case has been diagnosed as aleukemic lymphadenosis. A discussion on the origin and nature of the proliferating cells is presented with the tentative conclusion that they are derived from the multiplication of the small lymphocytes. Two cases of endothelioma of lymph nodes by Ewing are cited. Littoral cell sarcoma appears to be a more suitable designation for tumors of this kind. In one case there was universal enlargement of the lymph nodes, in the other there was localized growth. Histologically, the cases are characterized by the presence of large polyhedral cells with hyperchromatic nuclei which show mitoses. In view of the resemblance of their microscopic picture to secondary

carcinoma a careful search was made for a primary focus, but none was discovered. Attention is drawn to some peculiar clinical and histologic features of this type of new growth and its association with chronic granulomatous infections. The other two cases are of systemic enlargement of the lymph nodes of neoplastic nature. The cells in one case were elongated and spindle shaped, whereas in the other they were more rounded but some of the cells were spindle shaped. Reasons are advanced for their derivation from the reticular cells. Tumor is named reticulum cell sarcoma. A classification of the hyperplastic and neoplastic conditions of the lymph nodes is given.

Integration of Endocrine System — Langdon-Brown believes that there is an autonomous activity of the glands of the endocrine system according to the steady biochemical demands of the body but that their activity can be profoundly modified and extensively controlled by centers in the diencephalon which are largely concerned with emotional expression. These centers may operate directly through the sympathetic nervous system or indirectly through the chemical activities of the anterior pituitary. The anterior pituitary forms two basic secretions probably of a protein character, one being stimulating, the other inhibitory, in effect. They correspond to Sharpey-Schafer's original distinction between a hormone and a chalone. The former may be produced by the eosinophil, the latter by the basophil cells. These basic secretions are capable of chemical modification according to the needs of the body and are then ready to stimulate or restrain the secretion of simpler hormones by the other endocrine glands, including the postpituitary. It may be, as Zondek maintains that hormones circulate in an inactive form, becoming activated only when they reach their destination. This might explain some of the observations on the alleged hormone antihormone linkage. Their destination is decided by some peculiar receptive capacity in the structure on which they act, catalytically or otherwise. What determines that receptive capacity is not known as yet. But the whole process appears to be a special case of the general law that nervous stimuli, whether passing from the diencephalon to the pituitary or down neurons to preganglionic and postganglionic endings, act through the intermediary of chemical substances locally produced. Further support for this view may be found in the fact that in one instance epinephrine is the final product of either hormone or nervous activity.

Congenital Abnormalities in Genito-Urinary Tract — In an analysis of 500 consecutive cases referred for intravenous pyelography, Barclay and Baird have found the following congenital and other abnormalities: unilateral fused kidney showing two normal ureteral orifices with the left ureter crossing to the right side, congenital absence of the left kidney with complete reduplication of the pelvis and the ureters of the right kidney, six cases of bilateral double ureters and pelvis (two with complete and four with incomplete reduplication), seven cases of unilateral double ureters and pelvis (two with complete and five with incomplete reduplication), a case of probable valvular ureteral obstruction and two cases showing unilateral true renal ptosis. The possible production of the foregoing anomalies is discussed.

Membranous Oropharyngitis — During the last three years Hiller has observed five cases of a condition which he terms a membranous oropharyngitis. Actual organisms found on culture included hemolytic streptococcus, *Streptococcus viridans*, short-chained nonhemolytic streptococcus, *Staphylococcus aureus* and albus, and pneumococcus. The organism that appears to be the most consistently present is a short-chained nonhemolytic streptococcus. The condition is apparently mildly infectious, as shown by one case the patient having contracted it from her son. The signs and symptoms show a good deal of local discomfort and dysphagia, the latter being especially marked when the soft palate is involved. Sometimes slight enlargement and tenderness of the upper cervical lymphatic glands occurs. All cases seem to show a tendency for the membrane to appear at first on the anterior pillar of the fauces, usually in discrete patches which may spread to the soft palate, to the tonsil and occasionally to the posterior pillar of the fauces. But the favored direction of extension is to the gums and into the gingivolabial folds. The membrane is a false one, moderately thin, white and opalescent and always sharply demarcated, its edges being surrounded by a thin band of hyperemia. It lifts easily but is followed by very free hemorrhage from the whole of the bared surface, and it soon reforms. Recrudescence and recurrence are apt to occur. The diseases for which the condition may most easily be mistaken are diphtheria and Vincent's angina. The membrane is paler than is usual in diphtheria, it lifts much more easily and there is no constitutional disturbance. Further, there is more membrane present elsewhere than on the tonsils. A bacteriologic examination is always essential. Diphtheria antitoxin does not have the slightest influence on the condition. A combination of brilliant green and crystal violet is practically a specific for the condition. The following is the formula used for swabbing once or possibly twice a day: 2 per cent crystal violet, 2 per cent brilliant green, 48 per cent ethylic alcohol and 48 per cent water. This quickly clears up the faucial lesions, but those of the gums and the gingivolabial folds take longer. Overtreatment may be responsible for a prolonged course. In addition to the foregoing applications, the following paint is applied twice daily: 3 drachms (12 Gm.) each of tincture of ipecac and of solution of potassium arsenite and 1 ounce (30 cc.) of glycerin. In order to prevent infection of others, sterilization of the patient's articles should be enforced.

Efficacy of Acetylcholine in Treatment of Traumatic Epilepsy, Fribourg
Blanc Lassale and Passa —p 1892

Nonurate Azotemia—Nonnenbruch and Weisav calculated the blood urea by the xanthidrol method of Fosse or the micro method of Bang. The total nitrogen was determined in the trichloroacetic acid filtrate by the semimicro method of Kjeldahl. By these means they were able to measure the relative proportions of urea and nonurate nitrogen. Their observations were therefore divided into those in which there was a primary variation in the urea level and those in which the residual nitrogen was the first to vary. They concluded that increase of the residual nitrogen corresponds in liver disease to a lowering of the general condition and reveals a disorder of protein metabolism. The increase in residual nitrogen can also be the result of excessive urea elimination in the course of polyureas. An elevated level of nitrogen can be lowered by all the procedures which increase the level of urea that is accompanied by improvement of the general condition. Increase in the residual nitrogen produced by the administration of amino acids produces a decline in the general condition. Urea, on the contrary, even in small doses, can produce a sudden drop in the residual nitrogen and improve the general condition. In all cases of increased residual nitrogen and especially in liver disease, attempted treatment with urea and hepatic extracts is indicated.

Treatment of Bone Inflammations of War—The men who sustained fractures during the war which in subsequent years caused pain, fistulas and other signs of nonhealing are the subject of Sarroste's study. He believes that the term chronic traumatic osteomyelitis is inexact and that the appellation given by him is more appropriate. Four clinical forms can be identified: late single infections, multiple infections, permanent fistulization and intra-osseous abscess. The infection progresses from the surface of the bone into the deeper portions, following the fissures and resulting in local calcium disorders, vascular changes and necrosis. Hence the two classic reactions of bone are present side by side—rarefaction and condensation. Treatment of these late processes has always been difficult and unsatisfactory. A judicious prophylactic treatment of a recent fracture would seem to be the most important factor. In spite of careful handling, these late lesions have occurred in about 30 per cent of the war fractures. The principal methods of treatment of these are the biologic with serums or vaccines, surgery of varying extent and physical therapy. The author feels that carefully chosen surgery is the most important of these methods.

Moist Bandage Schlafli —p 1234

Venous Pulse—Merkelbach points out that whereas three decades ago the registration of the venous pulse was frequently resorted to, it is only rarely done today because the electrocardiographic method has largely superseded it. Nevertheless the author maintains that registration of the venous pulse has still diagnostic significance in that it reveals the circulatory conditions in the right side of the heart and also the venous outflow from the large circulation. He describes the technique

of registration of the venous pulse and the normal venous pulse curve, and the time relation between venous pulse, cardiac sounds and electrocardiogram, then the venous pulse in valvular lesions, and reproduces various curves of the venous pulse of patients with mitral insufficiency, tricuspid insufficiency and absolute arrhythmia, or nonsyphilitic aortic insufficiency. He admits that in the diagnosis of rhythmic disturbances of the heart registration of the venous pulse has long been superseded by electrocardiography, but he points out that, as Wenckebach and Winterberg have shown, registration of the venous pulse is of great value in early blocked auricular extrasystoles. In such cases the venous pulse curve clearly shows an A wave, whereas in the electrocardiogram the P wave does not have to be indicated, and under these conditions it is of course impossible for a deformity of the T wave of the preceding ventricular complex to become manifest in the electrocardiogram.

Edemepneurotic and Eclamptic Syndrome Without Convulsions Case G. Riesgo del Campo —p 1067

Postemotional Melanotic Pigmentation—Bonorino Urdondo and Gonalons say that melanoderma is a constant symptom of adrenal insufficiency caused by emotion. A few small pigmented patches, of a light brown at first, appear only on the face and then increase in number and size, intensify in color and cover new areas of the skin as the disease progresses. In rare cases the condition is complicated by a syndrome of hyperpressure, epistaxis, headache, dizziness and obnubilation or by the appearance of dull iridescent white patches of pigmentation during the early hours of the morning. The white pigmentation is caused by a reflex originating in the expansion, contraction and superposition of the chromatophore cells of the skin and the dermis. Its spontaneous appearance can be produced by subjecting the patient to sudden emotion, such as that caused by an unexpected noise like an explosion. Postemotional melanotic pigmentation is caused by an insufficiency of the adrenal cortex, proved by the fact that the administration of cortical extract for a prolonged period of time (one year and a half in the two cases reported by the authors) results in recovery. Discontinuance of the treatment before complete recovery causes an aggravation of the adrenal disturbance manifested by the reintensification of the pigmentation and of the general symptoms.

Cholesterolemia and Arterial Hyperpressure—Domenech and Lafuente discuss the relation between the disturbances of the cholesterol metabolism and the etiopathogenesis of arterial hyperpressure. On reviewing the literature one observes first that the results reported regarding experimental production of hyperpressure by administering diets containing substances rich in cholesterol to herbivorous animals are not applicable to the development of arterial hyperpressure in hypercholesterolemia in man because the cholesterol metabolism of human beings is entirely different from that of the lower animals; secondly that the figures given by several workers as representative of the frequency and intensity of hypercholesterolemia in hypertensive patients are conflicting, and, thirdly, that there is no reason on which the criterion of the origin of hyperpressure due to a direct action of cholesterol can be based. The authors made determinations of the cholesterol in the blood of fifty-two patients between 25 and 75 years of age suffering from hyperpressure. In 65 per cent of the group (thirty-four cases) hypercholesterolemia was present, but its intensity was not related to that of hyperpressure, and they were all suffering coincidentally from some other pathologic condition that seemed to be responsible for the presence of hypercholesterolemia. The pathologic conditions in the patients were a hypercortico adrenal syndrome in six cases, hirsutism in one, diabetes in six, hyperthyroidism in two, climacteric hyperpressure in thirteen, syphilis in twelve, cardiac insufficiency in ten and

pulmonary tuberculosis in two. The authors conclude that there is no etiopathogenic relation between hypercholesterolemia and arterial hyperpressure.

Tuberculosis Complicating Syphilis—Gomez and Gines made Wassermann tests of the blood serums of 1013 women suffering from various diseases with positive results in 110 cases. The sputum of eighty-nine patients in this group contained tubercle bacilli, twenty-four of whom suffering from fibrocaceous pulmonary tuberculosis were given a combined treatment of intravenous injections of neoarsphenamine (in increasing doses of from 0.15 to 0.6 Gm per injection once a week) and of double gold and sodium thiosulfate (in doses of 0.5 Gm per injection twice a week.) The total amount of neoarsphenamine administered during the treatment varied between 6 and 10 Gm. The arsphenamine and gold injections were made on different days and were well tolerated even by patients suffering from pulmonary tuberculosis complicated by laryngeal or intestinal tuberculosis. Hemoptysis did not follow the treatment. A severe hemorrhage was controlled in one case a few hours after the administration of an intravenous injection of neoarsphenamine. The treatment seemed to develop renal complications, which made their appearance in six patients of the group of twenty-four thus treated. Syphilis, as interpreted by the symptoms and by the results of the serologic reactions and pulmonary tuberculosis followed an independent and sometimes opposite evolution. The pleuropulmonary disease of patients in whom the examination of the sputum failed to show tubercle bacilli was considered of tuberculous rather than syphilitic origin because of the aspect and seat of the pulmonary lesions and of the history of the patient.

Treatment of Eclampsia with Solution of Magnesium Sulfate. D. P. Brownkin —p 141

Cholesterol Metabolism in the New-Born—Muhlbock found that the cholesterol content of the blood and serum of the umbilical cord is unusually low in comparison with that of the maternal blood. The esterification ratio in the umbilical serum is the same as in the maternal serum. The percentage of free cholesterol in the blood of the umbilical cord is greater than that in the maternal blood. This is explained by the larger number of erythrocytes that contain only free cholesterol. In the new born there is a considerable increase in the cholesterol content during the first few days of life. It begins a few hours after birth and reaches its maximum on the second or third day of life. In the blood as well as in the serum this increase is almost entirely the result of an increase in free cholesterol. The author discusses the various causes of the increase during the first few days of life but reaches no satisfactory explanation. In infants with icterus neonatorum and without it he found no difference in the height of the cholesterol values or in the esterification ratio. In this connection he discusses icteric conditions in adults and shows that icterus neonatorum cannot be caused by biliary stasis (as had been assumed by some) but must be the result of hematogenic factor.

Treatment of Trichomonas Vulvovaginitis—Werbatus and Kritschewski point out that the therapeutic effect of silver solutions is largely dependent on their degree of dissociation. They cite Jermolajew's studies, which disclosed that the presence of ammonia is important for the action of silver salts. In preparing the so-called ammonia silver salts, silver nitrate serves as the basic substance. It is first transformed into some form of silver salt, such as silver chloride ($\text{AgNO}_3 + \text{NaCl} = \text{AgCl} + \text{NaNO}_3$). This salt is then dissolved in ammonia ($\text{AgCl} + [\text{NH}_3]_n + \text{H}_2\text{O}$). In the solution thus obtained, the silver plays the part of the more active ions (cations) and the chlorine the part of the less active ions (anions). The authors used the freshly prepared solution for the treatment of women with trichomonas vulvovaginitis. The treatment consisted of three phases: (1) the vagina was irrigated with 1 liter of a 1:20,000 solution of ammonia silver salt, (2) enemas of 100 cc were given with a 1:40,000 solution of the same preparation without previous evacuation of the bowel, (3) a cotton tampon saturated with the 1:20,000 solution was left in the posterior vaginal vault for from twelve to eighteen hours. This procedure was repeated daily for about two weeks. Every fifth day the vagina was examined for the degree of purity and the presence of *Trichomonas vaginalis*. The authors obtained good results with this method.

Rôle of the Brown-Pearce Tumor in Experimental Studies—Bauer and Deckner studied the biologic and pathologic characteristics of the Brown Pearce tumor in 200 rabbits. They conclude that this neoplasm is a primary carcinoma of the skin in which the malignant condition is much greater than that of most growths found in man. The fact that it can be readily transplanted and that it gives rise to early and widespread metastases makes it particularly valuable for purposes of experimental study. Reinculation is accomplished by removing tissue from a metastatic growth under aseptic precautions, making an emulsion of it in physiologic solution of sodium chloride and injecting it into the testicle or into a vein. Inoculation into the brain the anterior chamber of the eye and under the skin was found less advantageous. The histologic structure of the tumor is that of an immature skin carcinoma; the cells of which possess no definite arrangement because of the almost total absence of stroma. The tumor metastasizes early and with great rapidity. The stormy growth of its cells is, however, accompanied everywhere by necrosis. The metastases spread by the lymphogenous and the hematogenous routes. The authors studied the questions of the preservation of individual characteristics on the part of the cancer cells of the increase in the malignant condition and of predisposition or resistance to the tumor. They found that the tumor cells retained their original characteristics after fifteen years and many reinculations. They may in a sense be considered potentially immortal provided reinculations into new organisms are kept up. The virulence has increased with time. Nearly all types of rabbits proved susceptible, although resistant types were occasionally encountered. The influence of individual differences and of external conditions such as season or light played a subordinate part in the question of immunity to the tumor. In the opinion of the authors the tumor offers great possibilities for investigation of the value of roentgen therapy, the hereditary biologic characters of cancer and the question of inheritance of predisposition to cancer as well as of the possibilities of chemotherapy.

Calcium Metabolism and Surgery of Parathyroids—Mandl states that generalized fibrous osteodystrophy or Recklinghausen's disease of bones constitutes a definite disease that can be diagnosed correctly in most instances. In the majority of such cases an enlargement of the parathyroids is found when operation is performed. Complete restoration to normal follows

the removal of the parathyroids. In a small number of cases with a clearly established diagnosis, a parathyroid tumor was not found at the time of operation. It is assumed that in such cases there may exist an enlarged but misplaced and therefore inaccessible parathyroid body. The removal of a normal parathyroid, however, leads even in these cases to a cure or at least to an improvement. Cases have been reported in which the removal of normal parathyroid tissue, in the absence of a parathyroid tumor, failed to cure the existing generalized bony dystrophy. A theoretical explanation of such cases is the possibility of some other endocrine influence on calcium metabolism than that of the parathyroids, or the more simple possibility of the existence somewhere in the body of misplaced hyperfunctioning parathyroid tissue. The fact that improvement has taken place following the removal of normal parathyroids in cases of ankylosing arthritis or in scleroderma, conditions in which the calcium metabolism is not disturbed, suggests that the parathyroids may have other functions besides that of regulating the calcium metabolism. Decalcination by means of parathyroid extract is worthy of trial in cases of hypercalcemia with bony changes, though its effects are not as striking or lasting as those of parathyroidectomy. Localized fibrous osteitis and Paget's osteitis deformans are not in any way related to Recklinghausen's disease of the bones. It is, however, probable that Paget's disease is related in some way to the parathyroids.

- *Differentiation of Benign and Malignant Hemorrhages of Gastrointestinal Tract I Boas—p 2003
- *Trichotillomania C L Karrenberg—p 2006

Hemorrhages in Gastro-Intestinal Tract—Boas shows that the methods formerly employed for the demonstration of blood in the feces can no longer be considered adequate. In addition to the demonstration of hemin, it is necessary, particularly in the case of a strongly positive peroxidase reaction to search also for occult hemoglobin and its derivatives. The first demonstration of hemoglobin does not make possible a differentiation of malignant and benign hemorrhages of the gastro intestinal tract. Serial examinations are more valuable if they reveal a gradual subsidence of the hemoglobin. A hemorrhage of benign origin is likely whereas the continuous admixture of hemoglobin makes a malignant hemorrhage probable. However the behavior of the stercoporphyryns is even more important. In the case of benign hemorrhages the porphyrin content of the feces particularly their content in deuteroporphyrin and protoporphyrin is usually low whereas in malignant hemorrhages it is usually considerably increased, irrespective of the amount of hemin products. For the approximate quantitative determination of the stercoporphyryns the author found helpful the use of a method that he designates as "shake out number." He also stresses that the heretofore neglected spectroscopic and spectrochemical methods should be used more widely.

Trichotillomania—Karrenberg describes the case of a boy, aged 12, with a peculiar type of loss of hair. The younger sister of the boy also had a peculiar type of alopecia. The skin seemed normal, there was no itching and the shape of the hairless area indicated an artefact. The children were carefully watched and it was found that the boy pulled out his own hair as well as that of his sister. The hair was cut short and the boy was admonished to discontinue the practice. The hair grew again. In this connection the author calls attention to Hallopeau's report on trichotillomania, in which the disorder was considered a disease entity in which extreme pruritus is the primary symptom. Later reports by several other investigators indicated, however that trichotillomania is not so much a disease entity as a symptom that becomes manifest in various disorders, such as idiocy, dementia, hysteria, neuropathy, chronic alcoholism, compulsion neuroses, sexual neuroses and psychic depressions. The disorder has been

observed also in persons without mental disturbances. The author relates a case in which trichotillomania concurred with syphilitic alopecia areata. The author points out that in cases in which a mental disorder is the underlying cause, psychiatric treatment will be necessary.

- *Change in Action of Ovarian Hormone and of Gonadotropic Portion of Anterior Lobe of Hypophysis by Disturbance in Acid Base Equilibrium K A Bock—p 1750

Causes of Sodium Chloride Requirements—Glatzel admits that it is necessary to restrict the intake of sodium chloride in some disturbances, but points out that it has medicinal value in other conditions. His studies are concerned with the sodium chloride requirements of healthy persons. First he reports observations that refute Bunge's theory, according to which sodium chloride consumption is known only among peoples who subsist mostly on vegetable foods, that is, on foods with a high potassium content. The author found that a diet with high potassium content does not lead to loss of sodium and concludes that Bunge's theory does not explain the sodium chloride requirements. Since a number of ethnologic, historical, physiologic and clinical observations indicate connections between the sodium chloride and the carbohydrate metabolism, he decided to investigate this problem, particularly the cleavage of the polysaccharides by the salivary amylase. On the basis of the results he obtained with several test methods, he concludes that the diastatic cleavage of the polysaccharides is greatly promoted by sodium chloride. He found that sodium chloride accelerates the action of the diastase as such and that it causes the secretion of a saliva that has a stronger fermentative action. He points out that quite similar conditions have been found in the pancreatic and the hepatic diastase.

Action of Hormones in Disturbances of Acid-Base Equilibrium—Bock shows that the secretory glands are not only related among themselves but also influenced by factors such as the sympathetic nervous system, the acid base economy and the electrolyte constellation. He investigated the dependence of the action of the ovarian hormone on the hydrogen ion concentration of the animal organism. For these studies he used mature castrated white mice. He observed that estrus could be elicited with 0.8 mouse unit in castrated mice that had received an acid diet whereas in case of an alkaline diet signs of estrus did not even appear following the administration of 14 mouse units. In studies on the dependence of the action of the gonadotropic hormone of the anterior lobe of the hypophysis on the hydrogen ion concentration of the animal organism, the author used infantile female mice. Here again he obtained unequivocal results. Animals that had received an acid diet showed spots of blood in their ovaries when only 0.6 mouse unit of gonadotropic substance had been given, animals receiving an ordinary diet showed this reaction in response to 1 unit and animals on an alkaline diet showed the spots when 1.2 units was given, and, in order to elicit estrus, it was necessary to give still larger doses. The author thinks that these observations may prove useful in the endocrine therapy of human subjects.

- *Vitamin C Requirements During Pregnancy and Lactation W Neuweller—p 1793

Vitamin C Requirements During Pregnancy—Neuweller describes elimination tests on nonpregnant pregnant and lactating women, which he conducted in order to determine the vitamin C requirements during pregnancy and lactation. The

tests revealed that the vitamin C consumption is greater in pregnant than in nonpregnant women and that the vitamin C requirements are even greater during lactation than during pregnancy. He concludes that the danger of C hypovitaminosis is especially great during pregnancy and lactation and that because of this it is important that pregnant and lactating women receive an adequate supply of vitamin C. If the diet does not provide sufficient amounts of the vitamin in the natural form (from fruits and so on), the vitamin C may be given in the form of a vitamin C preparation.

*Typical Sport Injury of Ankle Joint in Football Players A. Lersch
—p 1645

Significance of Pituitary Basophilism —Kraus calls attention to studies indicating that pituitary changes particularly pituitary basophilism play a part in the pathogenesis of nephropathy and eclampsia of pregnant women. He also cites studies disclosing that an increase in the basophilic cells of the hypophysis is observable not only in chronic nephritis and in various forms of contracted kidney but also in normorenal patients with dementia paralytica, so-called constitutional obesity, syphilitic mesoarteritis, chronic alcoholism or essential hypertension, and even under normal conditions in persons of the athletic type, particularly in those whose weight is somewhat excessive. The fact that the majority of the aforementioned disturbances are found chiefly in persons with a hypersthenic habit indicates that constitutional factors play a part in the increase in the basophil cells of the hypophysis. Moreover, the author found that pituitary changes are frequently accompanied by adrenal changes and that there is a relation to conditions of the blood pressure and to the fat and cholesterol metabolisms. However, although admitting a relationship between pituitary basophilism and such disturbances, he doubts the pathogenic significance of pituitary basophilism. He cites factors that contradict the pituitary genesis of eclampsia and of hypertension and shows that the pituitary basophilism observed in the various disturbances that are accompanied by hypertension as well as in constitutional obesity is only an occasional result but not the cause of these disturbances. With regard to the invasion of basophil cells into the posterior lobe of the hypophysis in cases of eclampsia, he says that there is not necessarily a direct connection between the two even as the manifestation of a compensatory process. He thinks that the increased invasion of basophils is due to the fact that the majority of women with eclampsia are obese (73 per cent according to one report) and that obesity is accompanied by pituitary basophilism in about 80 per cent of the cases. Moreover, since in many cases of eclampsia parenchymatous nephritis and contracted kidney had existed before the increased number of basophil cells could also be related to the renal disorder without having a causal connection with eclampsia.

Injury of Ankle Joint in Football Players —Lersch reports that he has observed cartilage bodies in the ankle joint of three young men who were football players. The first of the cases is described in detail because it illustrates the pathogenesis of the free joint bodies. The process begins with changes in the articular cartilage indicated by an indefinite outline and by excrescences and then the degenerated cartilage becomes gradually detached until finally there is a freely movable body. In this case as well as in the two other cases the bodies were removed by a surgical intervention so as to avoid incarceration in the ankle joint. In the course of examinations of other football players the author observed twelve others with changes at the osseocartilaginous boundary of the talus. These men, however, made no complaints, and therapeutic intervention was therefore dispensed with.

Action of Mustard Plaster on Skin Y. Hiro and M. Yamada —p 109

Lymphogranulomatosis of Lung During Childhood H. G. Huber —p 126

*Causes of Infant Mortality O. Savi —p 136

Cardiac Changes in Children with Goiter —Viethen says that Feer's observations of cardiac enlargement in new-born infants and nurslings with goiter was not corroborated by all investigators. Since this problem is of considerable clinical interest, the author made clinical and roentgenologic studies on its incidence and development in 177 children with goiter: twenty-three new-born, eighteen nurslings fifty-five up to the age of 10 years and eighty-one between 10 and 15 years. He observed cardiac enlargements in the new-born and in nurslings, but the incidence was not quite as high as reported by others. Pathologic anatomic studies revealed a larger weight of the heart in the new-born with goiter than in those without goiter. This corroborated the roentgenologically observed enlargements of the heart. In children of school age, the cardiac enlargements are no longer as frequent as in young children. However, roentgenoscopy disclosed important changes in the shape of the cardiac shadow in about 25 per cent. Electrocardiographic studies on new-born infants, nurslings and older children with goiter gave no definite indications of toxic impairment of the heart. The author concludes from this that in these children the cardiac changes are a result of mechanical pressure of the goiter on the cervical organs.

Static Infantilism —Flusser says that the term static infantilism was first used by Thomas for that condition of the static capacities in older nurslings or in small children which is observed in cerebral diplegia (Little's disease). It becomes manifest in an increased tension of the muscles of the extremities and a relaxation of the muscles of the trunk and neck. This behavior of the musculature dysmyotonia, is a physiologic condition during the first few months of life but should have disappeared at the end of the first half year of life. If it persists longer Little's disease must be thought of but, if this disorder can be excluded, an abnormal behavior of the musculature is frequently interpreted as rachitic myopathia. However, the author emphasizes that rickets is characterized by a lax hypotonic musculature of the extremities and that an increased tonicity cannot be ascribed to rickets. Moreover, simultaneously existing rickets of the bones does not justify the interpretation of changes in the musculature as rachitic. The main part of the author's report is concerned not with static disturbances that are the result of rickets or of abnormal conditions of the central nervous system but rather with a form of static infantilism characterized (1) by persistence beyond the normal period of the tonicity of the muscles and of the static capacities that exist during the first few weeks of life, (2) by abnormal smallness of the external genitalia, and (3) by insufficient longitudinal growth. Another symptom that is rather frequent in these children is cracking in the joints in case of voluntary, active movements. After pointing out that he has observed seven such cases within the last twelve years he gives a more detailed discussion of the symptoms and reports observations he made in some of his cases. He is convinced that the concurrence of the three symptoms dysmyotonia (with or without articular noises), microgenitalism and retardation in the longitudinal growth is not accidental but is of a constitutional nature. He hopes that his report of as yet incomplete observations will stimulate observations on a larger clinical material.

Causes of Infant Mortality —Savi summarizes his investigations as follows: 1 Up to 1925 the infant mortality in Prague showed a constant decline, but after that it increased again and reached a new peak in 1931, which from 1932 to 1934 was followed again by a declining tendency. The curve indicating stillbirths showed a similar behavior. 2 The mortality of nurslings and of the new-born and the number of stillbirths show a dependence on social factors. 3 The number of stillbirths increases with the size of the city except that in cities of more than 100,000 inhabitants the percentage shows

again a slight reduction. 4 The chief causes of stillbirths and early deaths are, in the order of their importance, debility, asphyxia, birth trauma, syphilis and obstetric operations.

*Scarlet Fever Conjunctivitis H. Otto—p. 1987

Albuminuria of Psychic Origin G. Buchner—p. 1988

Scarlet Fever Conjunctivitis—Otto points out that the majority of infectious diseases are accompanied by conjunctivitis but that it is frequently asserted that conjunctivitis does not occur in scarlet fever. Moreover, the presence of conjunctivitis is by some interpreted as a sign that the existing disorder is not scarlet fever. The author's observations, however, indicate that conjunctivitis is not as rare in scarlet fever as has been asserted. Of 891 scarlet fever patients who were treated at his clinic, fifty-two had a conjunctivitis (almost 6 per cent). After mentioning the various morphologic types of scarlet fever conjunctivitis, he says that the time of onset and the duration of the conjunctivitis differ considerably. There is an early and a late form. The early form develops within the first six days, frequently together with the exanthem, and persists from two to sixteen days. The late type begins between the fifteenth and fiftieth days and lasts for from eight to twenty-five days. In the author's material the early form was the most frequent. He reviews and evaluates various theories of the etiology of the conjunctivitis of scarlet fever and points out that these theories disregard the eosinophilia in the blood which to him is a sign of an allergic condition. He considers the conjunctivitis a manifestation of an allergic reaction.

Blood Transfusion and Internal Diseases—Blumberger has obtained satisfactory results with the citrate method. He recommends it in severe cases of pernicious anemia. For aplastic forms of anemia, blood transfusion has likewise been recommended but opinion differs about its efficacy in these disorders. He says that the leukemias are not influenced by blood transfusion but that the secondary anemias that may accompany leukemia are favorably influenced. He does not consider blood transfusion a reliable method for the treatment of agranulocytosis but admits that favorable results have been reported. In thrombopenic conditions blood transfusion has likewise been known to produce good effects. Moreover blood transfusion has proved valuable as a blood substitute and for hemostatic purposes. In this connection the author mentions severe gastric and intestinal hemorrhages, severe loss of blood in hemophilic patients and parenchymatous hemorrhages. He shows that in early carcinomatous hemorrhages blood transfusion may eventually restore the patients to such an extent that surgical treatment can be resorted to. He estimates the value of blood transfusion in various infectious diseases. His own observations were made only on patients with sepsis and with infectious granuloma (Hodgkin) and his results were not greatly encouraging. Other infectious diseases in which blood transfusion has been known to produce favorable results are scarlet fever, measles, chickenpox, diphtheria and typhoid. In these cases it is usually the object to transmit the blood of persons who have had the corresponding infectious disease in the hope that the antitoxin content of the donor's blood will be effective. However the author stresses that other treatments, particularly serums, are usually available in these disorders. He does not entirely reject the use of blood transfusions for these conditions but thinks that it should be used sparingly so as not to bring the method into discredit through misuse.

Suppurating Meningitis and Scarlet Fever—Zischinsky gives the histories of three cases of suppurating meningitis in scarlet fever and shows that all were of the primary (metastatic) type. One of the patients recovered. As regards the pathogenesis of suppurating meningitis in scarlet fever, two types can be differentiated, the primary or metastatic type and the type that develops by direct conduction, in which case the ear plays the most important part, the accessory sinuses being of much less importance. He points out that in discussions with otologists the question is often raised as to whether there is really a metastatic meningitis in infectious diseases, many of them being of the opinion that the pathogenesis is usually otogenic. To this he replies that every experienced pediatrician will admit that there is a metastatic form. As far as the author's own observations are concerned, he thinks that the metastatic form is even the more frequent. He admits that this greater frequency is more evident in whooping cough than in scarlet fever, since suppurating meningitis is comparatively rare in the latter condition.

*Successful Use of Diiodotyrosine in Some Internal Disorders A. Edelmann—p. 1518

Insulin in Treatment of Menstrual Disturbances—Klawen points out that a number of investigators have tried insulin in the treatment of menstrual disturbances and that he has resorted to their prophylactic treatment with insulin. He found that this treatment normalized the flow in some cases of profuse menstrual bleedings and particularly in prolonged bleeding. He considers it especially important that the treatment was helpful in cases of polymenorrhea. It proved possible to prolong the interval from fourteen to twenty, twenty-four and finally twenty-eight days. The interval was normalized and the period of bleeding was shortened in twelve out of fifteen patients with polymenorrhea and hypermenorrhea, but the intensity of the hemorrhage was influenced only in half the number. In twelve cases of juvenile hemorrhagic metropathy the results were likewise favorable, but in preclimacteric hemorrhagic metropathy the effect was not so good, in that only some of the patients responded. The latter were usually women who had undergone surgical treatment for gastro-intestinal ulcer or for cholelithiasis. All had lost weight and this emaciation was accompanied by menstrual disturbances, that is these cases were characterized by secondary, insulogenic menstrual anomalies. Another group of women in whom polymenorrhea and hypermenorrhea were favorably influenced by insulin therapy were those who had a hereditary history of diabetes or those who later developed diabetes. Women of the preclimacteric period with hemorrhagic metropathy who did not have the aforementioned symptoms (emaciation, metabolic disturbances, cholecystopathy and so on) did not respond so well to insulin treatment. The insulin dosage was adapted to the body weight, the age and the blood sugar value. Generally the daily dose varied between 15 and 30 units but in some instances as much as 40 or 50 units was given. The injections were begun five days before the expected menstruation and were continued for four or five days. The author points out that he found insulin effective also in two women with emaciation, anorexia and amenorrhea. He shows that the mechanism of the insulin action is extremely complicated. He mentions the metabolic component, the regenerative effect, the influence on the sympathetic nervous system and on the process of follicle maturation and the formation of the corpus luteum. An influence on the anterior lobe of the hypophysis is likewise possible.

Diiodotyrosine in Internal Disorders—Edelmann points out that, although iodine medication was known to be effective in many disorders, its use was avoided because of the danger of exophthalmic goiter. Since diiodotyrosine is as effective as inorganic iodine but does not involve the same danger of harmful effects, the author decided to use it in conditions in which

iodine therapy promised favorable results. On the basis of his observations he considers the use of diiodotyrosine indicated in so called rheumatic disturbances that are caused by metabolic disorders, particularly uric acid diathesis, in the rheumatic disturbances that are caused by endocrine disorders in allergic conditions, particularly bronchial asthma and vasomotor rhinitis, in tachycardias of thyrotoxic climacteric or of unknown pathogenesis, in some cases of diabetes, in goiter, and preparatory to thyroidectomy.

The Hypophysis and Diabetes Mellitus—The survey of Anselmino and Hoffmann on the present knowledge of the modification of the carbohydrate metabolism by the anterior lobe of the hypophysis reveals that this lobe acts on the carbohydrate metabolism by means of a number of hormones. Since it has been possible to produce artificial diabetes in animals by the administration of various anterior pituitary extracts and since numerous clinical observations indicate a hypophyseal involvement in human diabetes mellitus, the authors have tried to demonstrate a disturbance of the hypophyseal regulatory mechanism in patients with diabetes mellitus. They detected a pathologically increased elimination of the anterior pituitary hormones of the fat and carbohydrate metabolisms in the urine of such patients and also the presence of an increased amount of these hormones in the blood while the patients were fasting. From these observations the authors conclude that the hypophyseal regulatory mechanisms are severely disturbed. They discuss the metabolic action of these two hormones and show that their action corresponds to the most important clinical symptoms of diabetes mellitus. They reach the conclusion that a functional disturbance in the hypophysis plays an important part in the development of human diabetes mellitus, which, as regards its pathogenic significance, places the anterior lobe of the hypophysis directly beside the pancreas.

Rhythmic Function of Human Liver—Jores investigated the rhythmic function of the human liver by determining at four hour intervals, within the twenty-four hours of the day, the bilirubin content of the blood, the urobilinogen elimination and the pigmentation of the urine. In healthy persons who received a normal diet the curve indicating the bilirubin content of the blood had two maximal values at noon and at midnight. The minimal values were observed at 8 a. m. and 8 p. m. The urobilinogen elimination in the urine shows a maximum between noon and 4 p. m. and a minimum during the night and early morning hours. The urinary pigment shows a maximum from 4 to 12 a. m. and a minimum between 4 and 8 p. m. In order to determine whether this rhythm is influenced by the intake of food tests were made on patients with ulcer, who were fed by means of a duodenal tube. The patients were given the same amounts of a food mixture at two hour intervals in the course of the twenty-four hour period. It was found that this manner of food intake did not influence the rhythms. The same rhythms could be detected in patients with various types of jaundice. In view of the fact that the bile pigments originate in the blood pigments it seems possible that the described rhythms might be connected with a rhythmic blood destruction. The author investigated this problem by determining the resistance of the erythrocytes in the course of the twenty-four hour period, but he found no fluctuations and he concludes that the aforementioned rhythms are connected with a corresponding rhythmic activity of the liver. He points out that the rhythmic formation of the liver is important for diagnosis and therapy and for the twenty-four hour periodicity in general.

Congenital Heart Defects—Steinberg and Wiesner describe three cases of congenital cyanosis: one in a girl aged 19 and two in youths aged 20 and 19 respectively. Two of the patients died. The necropsies showed that the first patient had a stenosis of the pulmonary artery and a defect of the ventricular septum with displaced aorta. In the second patient there was a transposition of the large vessels, and the auricular septum was almost completely missing. The third patient had a defect of the auricular septum. The authors review the literature on the diagnosis of congenital cardiac defects. They show that the combination of several anomalies may make the diagnosis extremely difficult. They stress that the clinical aspects, percussion and auscultatory phenomena are the most important guides in the diagnosis.

Porphyrin in Urine and Lead Poisoning—Franke and Litzner emphasize that it is highly important to determine the porphyrin content of the urine for the early recognition of incipient lead poisoning. They show that in the absence of severe hepatic disturbances or of acute porphyria, daily porphyrin values of 500 micrograms (0.5 mg.) or a porphyrin content of 50 micrograms or more per hundred cubic centimeters indicate an impairment of the bone marrow by lead. They give a tabular report of the results of their tests on forty-two workers whose occupation exposed them to lead poisoning. They found that the normal porphyrin elimination in the urine is considerably higher in healthy lead workers than in other persons. They mention observations on three men (two brothers and a son of one) which indicated that there is a familial sensitivity to lead. It was observed also that the efficacy of the treatment of lead poisoning can be determined on the decrease in the porphyrin elimination. The authors recommended that workers who come in contact with lead should be subjected to porphyrin tests of the urine at regular intervals at least during the first two years of such work. In this manner it will be possible to determine whether they have a hypersensitivity to lead.

Lead Poisoning and Porphyrin—Roth reports a case of lead poisoning in which he investigated the relation between lead poisoning and the elimination of porphyrin. Every day he determined the quantity of urine, the elimination of porphyrin in the urine, the specific gravity of the urine, the erythrocyte values, the hemoglobin content, the reticulocytes and the resistance of the erythrocytes. The results of these studies are recorded in a table that also indicates the porphyrin content of blood and feces. The porphyrin elimination in the urine and in the feces was greatly increased. In the erythrocytes the protoporphyrin was greatly increased. There was no clear parallelism between the clinical symptoms and the porphyrin elimination. The symptoms decreased at a time when the porphyrin elimination was still rather high. The injection of liver extracts had no noticeable effect on the porphyrin elimination.

Desensitization with Tuberculin and Immunity Against Tuberculosis—Selter and Weiland found that the desensitization of tuberculin-sensitive guinea pigs with increasing doses of tuberculin does not impair the immunity of these animals against fatal superinfections. This indicates that sensitivity to tuberculin and immunity to tuberculosis are two distinct manifestations of the tuberculous infection which are not mutually dependent and have no functional relations.

Pathogenicity of Tubercle Bacilli of Mammals for Chickens—Contradictory statements of other investigators about the pathogenicity of mammalian tubercle bacilli for chickens induced Grünberg to investigate this problem. He

always succeeded in infecting chickens with virulent tubercle bacilli of the avian type. Of eight animals thus infected, five died as the result of the infection and on necropsy showed severe pathologic changes. Three survived, and, when killed from six to nine months after the infection, they were found to be tuberculous, although they had never shown tuberculous symptoms. Of ten chickens that had been inoculated with tubercle bacilli of the human type, two died, but only one of them showed signs of tuberculous infection. All other animals of this group were killed after nine months and at that time proved free from tuberculosis. Of the twelve chickens that were inoculated with bovine tubercle bacilli, six were undernourished at the time of infection, while the others were well fed. The first six died, but only four showed tuberculous changes. Only one of the six well fed animals became infected. The others were found free from tuberculous changes when killed six months later.

*Significance of Amenorrhea in Women with Pulmonary Tuberculosis F Gal—p 2973

Amenorrhea in Tuberculous Women—Gal describes studies showing that menstrual disturbances are comparatively frequent in pulmonary and in genital tuberculosis. However, he was unable to corroborate that the menstrual disturbance is more frequent in severe cases; that is that the amenorrhea is caused by the tuberculous virus. He gained the impression that the amenorrhea is not caused by the tuberculous disorder but by the pathologic constitution that predisposes to tuberculosis. The severe forms of uterine and ovarian tuberculosis are of course different in this respect, in these cases the amenorrhea is caused by the destruction of the functioning tissues of the uterine mucosa and of the ovary. The author thinks that in the majority of tuberculous women with amenorrhea the menstrual disturbance requires no treatment. In the rare cases in which the amenorrhea is the cause of severe symptoms of abolished function, injections of endocrine products or quartz lamp irradiations are often beneficial.

Cod Liver Oil Treatment of Wounds—Iost and Kochergin report 263 cases in which cod liver oil treatment was used. Of these, twenty-eight were chronic ulcers, twenty-five burns or frost bites, nineteen severe trauma of the soft tissues of the extremities, ten open amputation stumps, 150 fresh superficial wounds and forty suppurating wounds. Cod liver oil was applied as a paste, made with 100 cc of cod liver oil, 100 Gm of petrolatum 15 cc of a preparation containing vitamins, and 10 cc of Japanese wax. In their experience a local application of cod liver oil was definitely beneficial in chronic ulceration, burns, frost bites and recent trauma of soft tissues. They believe the effect to be due to the abundant vitamin A and D content of the cod liver oil. Vitamin D possesses the property of stimulating the growth of granulations and of the epithelium. They consider it possible that there exists in the pathologic lesions or traumatized tissue a lack of vitamin due either to interrupted supply or to an increased demand for vitamins. The authors demonstrated in their bacteriologic studies that cod liver oil lowers the vitality of pus-producing bacteria. The application of cod liver oil to the wounds in the form of a

paste is more efficient because the oil is kept in contact with all parts of the wound. Keeping the lesion at rest is an important element in the treatment and is accomplished by fewer dressings or by immobilization in a plaster cast.

Method for Bandaging Supracondylar Extension Fractures of Arm in Children L O Christensen—p 1216

Salt Deficiency, Dehydration and Acidosis—Kirk states that, whenever salt deficiency and dehydration are probable in surgical diseases, plasma chloride and plasma bicarbonate analyses are in order. Treatment consists in subcutaneous, intra venous or rectal administration of isotonic solution of sodium chloride (0.9 per cent). In grave cases from 3 to 5 liters is given daily 1 liter at each session, until the chloride values and the total salt content of the plasma become normal and a diuresis of from 1 to 2 liters daily is attained. The salt content in 1 liter of vomit being about the same as in 1 liter of plasma none of the amount of vomited matter aids in the daily establishment of the necessary salt dosage. Overdosage is prevented by examination of the plasma chloride values. In acidosis of nondiabetic nature due to loss of alkaline secretion or retention of acids, intravenous injections of isotonic solution of sodium bicarbonate (1.3 per cent) are given. Symptoms of dehydration, mainly oliguria and increased blood urea, are often present. If the dehydration is partly due to chloride deficiency, supplementary administration of isotonic solution of sodium chloride is desirable. If the acidosis depends on inanition, a solution of dextrose also is indicated. The author warns against subcutaneous injections of the bicarbonate solution and against sterilization of the solution by heating and states that the solution must be used within four or five days after preparation. The amount of bicarbonate indicated in any case can be approximately determined by application of Palmer and Van Slyke's monogram. The effectivity of the treatment may be controlled at any time by determination of the bicarbonate content of the plasma. As a rule 1 liter of bicarbonate solution is given at each session in the course of about twenty minutes. If cardiac complications are suspected, great care must be exercised and intravenous injections of larger amounts of fluid omitted. Six cases are reported.

Three Attacks of Agranulocytosis—Olsen has himself had three attacks of agranulocytosis the first a typical case in 1928 after use of allylisopropylbarbituric acid and aminopyrine for about two weeks and the second a slight recurrence with characteristic blood changes being the earliest cases of agranulocytosis reported in Denmark. Blood examinations from 1928 to 1931 showed normal relations. After a relatively small dosage of double gold and sodium thiosulfate given in sanatorium treatment of a fairly recent tuberculous infection in both lungs in 1931 a highly febrile condition developed with pronounced symptoms of metal poisoning, and agranulocytosis was established. The double gold and sodium thiosulfate is regarded as the etiologic factor. These instances apparently show that a person may have a specific form of sensitiveness to substances of different chemical composition and having reacted toward one substance with agranulocytosis, may react similarly toward other substances.

PRIMARY CARCINOMA OF THE LUNG

A DIAGNOSTIC STUDY OF ONE HUNDRED AND
THIRTY-FIVE CASES IN FOUR YEARS

Primary carcinoma of the lung is not a rare disease but constitutes about 6 to 8 per cent of all carcinomas.¹ In frequency it ranks next to malignant conditions of the gastro-intestinal tract. Twenty years ago only 5 per cent of the cases were diagnosed clinically, today about 50 per cent are recognized during life. After a ten year study of this subject we are convinced that at least 90 per cent of the cases can be diagnosed. The clinician who is familiar with the pathologic and clinical manifestations of primary lung carcinoma can recognize most cases from the history, physical examination and roentgen study. In some cases a bronchoscopic examination, injection of iodized oil or artificial pneumothorax will be necessary. The diagnosis can be confirmed by a biopsy of the frequently enlarged cervical or axillary lymph nodes, by microscopic examination of pleural exudates or pieces of tissue in the sputum, or by removal of a piece of tissue from a bronchus.

During a four year period we have studied 135 cases of primary carcinoma of the lung. Most of these patients were seen at the Cook County Hospital, the rest in private practice and in other hospitals. Seventy-four cases were confirmed by necropsy, twenty-six by biopsy and thirteen by bronchoscopy, and twenty-two were diagnosed from the characteristic clinical and roentgen manifestations. This study has indicated that cancer of the lung is one of the most important pulmonary diseases in people past 40 years of age. It must always be considered in dealing with cases of lung abscess, bronchiectasis, recurrent pneumonia, emphysema, hemorrhagic pleurisy and chronic pneumonia.

Pain in the chest or in other parts of the body, accompanied by a cough and bloody sputum and sooner or

later followed by dyspnea, is the cardinal symptom. An area of pulmonary infiltration or atelectasis, enlarged supraclavicular or axillary lymph nodes, a hemorrhagic pleural effusion, paralysis of a diaphragm or of one of the vocal cords, a Horner syndrome, and evidence of bone, brain, liver or other metastases make the diagnosis quite certain. Tuberculosis is usually easily excluded but may occasionally accompany lung carcinoma. The roentgen signs are diagnostic in a high percentage of cases. The bronchoscope is of great value in confirming the diagnosis and in treatment, but the correct diagnosis can be made in most cases without its use. The finding of carcinoma in a biopsy from an enlarged lymph node, a bronchus, tissue in the sputum, sediment from a pleural effusion, or a piece of tissue obtained by thoracotomy completes the diagnosis. We shall at this time discuss our observations, with special attention to the diagnosis of primary carcinoma of the lung, and shall publish a more complete study at a later date.

AGE, SEX AND RACE

Among our 135 cases we find that 72 per cent occurred between the ages of 41 and 60 years. Twelve patients, or about 9 per cent, were from 21 to 40 years old. Table 1 gives the age incidence.

Ninety per cent of all our patients were chronic smokers, and we believe that the inhalation of tobacco smoke may be an important factor in producing chronic irritation with epithelial metaplasia in the bronchi or bronchioles. There were only twelve cases, or 9 per cent, among Negroes, all of whom were patients at the Cook County Hospital, where about 30 per cent of all the patients are colored. There were 125 men and only ten women in our series.

PATHOLOGIC CHANGES

Certain pathologic changes in this series are of great importance from the diagnostic standpoint, and these will be considered. Of the 135 cases eighty-two, or 60 per cent, occurred in the right lung and fifty-three, or 40 per cent, in the left lung. In the seventy-four necropsy cases there were forty-two in the right lung and thirty-two in the left. The greatest number of carcinomas were found in the right upper lobe with twenty-four, left upper thirteen, left lower twelve, and right lower eleven. Seven involved the entire left lung and six the entire right lung. Only one was primary in the right middle lobe.

All carcinomas of the lung are bronchiogenic in origin.² They arise in the trachea, bronchi or bronchioles. There can be no carcinoma primary in the alveoli, as they have no epithelial lining. The tumors arise from a metaplasia of the basal cell layers of epithelium, less differentiated multipotential cells which can reproduce

columnar epithelium, squamous epithelium, or undifferentiated round or spindle cells. Such metaplasia of the bronchial epithelium has been found in influenza.³ Some tumors may arise from the mucus-secreting glands of the bronchi. There are, therefore, three types of carcinoma: (1) adenocarcinoma, (2) squamous cell and (3) undifferentiated round or spindle cell. In our seventy-four necropsy cases twenty-one, or 28 per cent, were adenocarcinomas, eighteen, or 24 per cent, were squamous cell and thirty-one, or 41 per cent, were undifferentiated round or spindle cell.

TABLE 1—Ages of the Patients

Age	Number of Patients	Per Cent
21 to 30	3	2.2
31 to 40	9	6.6
41 to 50	39	29.0
51 to 60	59	43.7
61 to 70	22	16.3
71 to 80	3	2.2

The round and spindle cell carcinomas are the ones which were in the past often erroneously diagnosed as lung or mediastinal sarcomas.⁴ All this type presented metastases at necropsy. All showed involvement of the bronchial lymph nodes. The abdominal lymph nodes were invaded in 50 per cent of the cases, the brain in 16 per cent and the bones in 21 per cent.

The adenocarcinomas are almost as malignant as the round cell form. All this group presented metastases. Bone lesions were most frequent, with 48 per cent of the cases showing bone metastases.

The squamous cell carcinomas are less malignant than the other forms and offer the best prognosis for early surgical removal. Still six of eighteen cases presented brain metastases. Metastases in the liver, kidneys and adrenals were only one-third as frequent as in the other types.

The great importance of the frequent lymphogenic and hematogenic metastases in the diagnosis of primary carcinoma of the lung will be emphasized when we discuss the different clinical types of this disease. Not only is dissemination by the blood stream (owing to the ready access of the tumor to the pulmonary veins and vena cava) a common occurrence, but also extension from the tracheobronchial lymph nodes to the periaortic, peripancreatic, perigastric, periportal and retroperitoneal nodes. The presence of abdominal tumor masses may easily lead to an erroneous diagnosis.

Of the seventy-four necropsy cases all but one presented metastases, and this case was a squamous cell carcinoma. A knowledge of the histologic types of lung carcinoma is of importance to the clinician as well as to the pathologist. The physician should order a biopsy whenever there are accessible cervical or axillary gland masses, pleural effusions, tumor tissue on bronchoscopic examination, or operation on the chest wall. Bone metastases, tumor tissue found during an exploratory laparotomy, or skin nodules may furnish material for the diagnosis. A knowledge of the three important histologic types is therefore of great diagnostic value. Undoubtedly in the past adenocarcinoma of the lung with abdominal metastases was sometimes mistaken for a primary carcinoma of an abdominal organ unless a complete and careful necropsy was obtained. We know that most of the round cell, oat cell, or spindle cell "sar-

comas" of the lung are really carcinomas of bronchogenic origin. A round cell carcinoma metastasizing in a lymph node may be mistaken for a lymphosarcoma.

Anatomically we have divided our cases of lung carcinoma into five types: (1) intrabronchial, (2) hilar or central, (3) intermediary, (4) peripheral and (5) lobar or diffuse. Such a division is of importance in the early diagnosis of this disease. The physical and roentgen changes, symptoms, and operability depend largely on the location of the tumor in the early stage. These types, of course, are not sharply defined and merge into one another with the progress of the disease.

Associated pathologic lung changes are very frequent and may mask the underlying primary disease. Lobar pneumonia and bronchopneumonia occurred in 28 per cent, chronic pneumonia in 20 per cent, and bronchiectases in 43 per cent. Abscess or gangrene, either in the tumor itself or in the surrounding lung parenchyma, developed in 20 per cent. Pleural involvement with a carcinomatous lymphangitis, hemorrhagic, serous or purulent exudate or marked thickening was found in 50 per cent of the cases at necropsy. Atelectasis of part of a lobe or an entire lobe was often due to bronchus stenosis. Active pulmonary tuberculosis was found in only three of seventy-four cases and is certainly not a factor in the causation of lung cancer. Pneumoconiosis was rare.

SYMPTOMS

The failure to recognize lung carcinoma more frequently can be attributed in part to the great variation in the symptoms of this disease. These symptoms depend on the location and size of the primary tumor, the secondary changes that so often occur, and the location of metastases. In a small group, about 15 per cent, the primary tumor produces no signs or symptoms. Some of these cases can be diagnosed by bronchoscopy if the lesion is in a large bronchus, but

this is seldom done when there are no pulmonary symptoms. This occult type causes symptoms when lymphogenic or hematogenic metastases develop.

In our large series of 135 cases sixty-nine patients, or 51 per cent, had chiefly extrapulmonary manifestations. The signs and symptoms were predominantly outside the lungs. Only sixty-six patients, or 49 per cent, had symptoms that were largely pulmonary. We have classified our cases into clinical types with reference to the outstanding clinical manifestations (table 4).

Pulmonary Type—In the pulmonary type the symptoms are usually a cough, hemoptysis, pain in the chest, and dyspnea. These symptoms in a person past the age of 40 are very suggestive of carcinoma of the lung. The average duration of symptoms at the time of the first examination was eight months. In a few cases the symptoms dated back three years or longer, and it is interesting that these were mostly cases of

TABLE 3—*Metastases in the Different Histologic Types of Lung Carcinoma*

squamous cell carcinoma. In other cases the complaints were of short duration, a few days to a few weeks, with onset with a chill and fever as in pneumonia. A history of repeated attacks of bronchitis, pleurisy or pneumonia was given by 25 per cent of the patients.

The cough is usually progressive and fails to respond to rest or medication. It is dry at first, later often productive of a blood-streaked mucoid or purulent sputum. In some cases there is a sudden onset of the cough with pneumonic symptoms. Because of the bloody sputum a diagnosis of tuberculosis is frequently made, although tubercle bacilli are absent. Later a brassy pressure cough, often with an asthmatic wheeze, causes great discomfort. A persistent cough was present in 106 of our 135 cases, about 80 per cent.

Hemoptysis is often the first symptom of lung carcinoma. At first the sputum is blood streaked only at intervals. Later a severe hemoptysis may occur. We have seen several cases in which there was fatal hemorrhage. Bloody expectoration in the absence of pulmonary tuberculosis or mycosis or cardiac disease is very suggestive of lung cancer. The sputum should always be carefully examined for tissue fragments. Fixation and microscopic sections may make the diagnosis certain. We have found tumor tissue in the sputum in several cases. Hemoptysis occurred in fifty-eight of our cases, or 43 per cent.

Pain is the second most frequent symptom. It is more continuous than in any other thoracic disease except possibly aortic aneurysm with bone destruction. The pain is sharp and lancinating and is usually due to involvement of the pleura, intercostal nerves or bony structures. Metastases in the spine and ribs are very frequent. In patients with pleural effusion the pain does not disappear with the development of the effusion but becomes more and more severe. Such continuous pain in the chest, in the absence of an aneurysm or metastases from some other source than the lungs, is almost diagnostic. Often the pain is aggravated or induced by percussion of the chest. This finding we consider highly significant. Thoracic pain occurred in seventy-nine, or 58 per cent, of all cases, and extra-thoracic pain in fifty-eight patients, or 43 per cent. Ninety-nine, or 73 per cent, suffered severe pain.

Dyspnea may be an early or a late symptom. It may be due to stenosis of a bronchus by the tumor or compression of the trachea or bronchi by lymph node metastases. With the dyspnea there is often an asthmatic wheeze or brassy cough. Other causes of dyspnea are large pleural effusions, pressure on the superior vena cava or pulmonary blood vessels, pericarditis, atelectasis, or acute or chronic pneumonia. Dyspnea was marked in seventy patients, or 52 per cent.

The general effects of lung carcinoma are mainly loss of weight, fever, weakness, night sweats, and fatigue. A leukocytosis is common. Clubbed fingers occurred in 15 per cent of the cases. The symptoms due to metastases or extension from the primary tumor are of great importance, as will be seen from a discussion of the other clinical types.

Osseous Type—This is one of the most frequent forms encountered by us. Of thirty-five patients with bone metastases among 135 cases, we have placed twenty-one in this group. The first complaint is sharp severe pain in the chest wall, often limited to certain ribs, or in the spine, skull, pelvic bones or an extremity. The patient may enter with a pathologic fracture, as did three of our patients. A careful history usually but not always elicits the presence of a cough or hemoptysis. Roentgenograms of the painful parts usually present the changes of osteolytic or osteoclastic metastases. There are irregular small or large areas of bone destruction. We have found them most often in the ribs, skull, pelvic bones, sternum, ends of the long bones, scapula and clavicle. Sometimes large soft tumor masses develop, which may be mistaken for a bone sarcoma. In all cases of osteoclastic bone metastases a lung carcinoma must be considered as the primary site. In our experience lung cancer is one of the most frequent causes of osteoclastic bone metastases. In the differential diagnosis of bone metastases breast, thyroid and kidney carcinoma, melanoblastoma, ovarian carcinoma, and any other malignant condition must be considered. We have recently had two cases of stomach carcinoma presenting bone metastases in the ribs, clavicles and spine.

Cerebral Type—This group is next in frequency. Twenty of 135 patients presented symptoms in the central nervous system. Of these we have included

TABLE 4—*Clinical Types of Lung Carcinoma*

	Cases	Per Cent
1 Pulmonary	66	49
2 Osseous	21	16
3 Cerebral	23	17
4 Cardiac	12	9
5 Gastrointestinal	11	8
6 Lymphoglandular	9	7
7 Hepatic	3	2

thirteen cases in this group because of the outstanding cerebral changes. Five of the patients were admitted to neurologic services. Some were at first diagnosed as cerebrospinal syphilis, meningitis, brain abscess, encephalitis, cerebral hemorrhage, or brain tumor. When a person of middle age has an abrupt onset of signs and symptoms of a rapidly developing intracranial lesion a metastatic lung carcinoma should be considered and the lungs carefully examined and roentgenographed. Any part of the brain or cord may be affected. The cranial nerve centers are often involved, or there is a hemiplegia. Headache is common. The patient may be admitted in coma. A careful neurologic exam-

ination is indicated in every patient with lung cancer. Brain metastases were found in eighteen of seventy-four necropsy cases, or 24 per cent. Not all these presented clinical symptoms.

Cardiac Type—This series includes twelve cases in which heart signs and symptoms were outstanding and the lung changes less evident. The heart, pericardium and great vessels are frequently invaded by the tumor. Cancer of the right upper lobe often compresses or invades the superior vena cava or innominate vein, with symptoms like those of a mediastinal tumor. The clinical picture of a right heart hypertension or decompensation has occurred in a number of cases. In two cases the pulmonary artery was surrounded and compressed, in seven the pulmonary veins were stenosed. The extensive perivascular carcinomatous lymphangitis may cause narrowing of many smaller pulmonary vessels. Infiltration of the pericardium and myocardium occurred in ten cases. Sometimes the inferior vena cava or hepatic veins are involved, producing hepatic enlargement and stasis with ascites, and edema of the lower extremities. The chief symptoms in this cardiac group are dyspnea, cyanosis, edema, cardiac enlargement and occasionally ascites.

Gastro-Intestinal Type—Here we have included eleven cases. The chief cause of the gastro-intestinal signs and symptoms is the presence of abdominal metastases. Thirty-eight per cent of our necropsy cases revealed metastases in the abdominal lymph nodes. These form huge masses in the periaortic, peripancreatic, perigastric and periportal nodes. The liver was enlarged in 24 per cent of all our cases and showed metastases in 40 per cent of the necropsy cases. In four cases a large nodular epigastric tumor was mistaken for a carcinoma of the stomach or colon. Even the roentgen examination may be misleading. We have seen filling defects due to compression or infiltration of the stomach wall. In two cases the metastases led to pyloric obstruction. In three, gastric or duodenal hemorrhages followed compression with secondary ulceration. With jaundice, which occurred in six cases, a carcinoma of the pancreas may be suspected. Nine of our patients complained of difficulty in swallowing, and in six of these the dysphagia was the first complaint. We were able to demonstrate compression of the esophagus by gland metastases in all these cases on roentgen examination with thick barium paste.

Lymphoglandular Type—This form is due to extensive metastases in the supraclavicular, cervical or axillary lymph nodes as well as in the deeper nodes. One of our most valuable aids in the diagnosis of primary lung cancer has been a careful examination for enlarged cervical or axillary nodes. A large hard node is frequently found above the clavicle or behind the head of the clavicle. The diseases that cause the greatest difficulty in differential diagnosis are Hodgkin's disease and lymphosarcoma. When a node is accessible, a biopsy should always be done. In nine of our cases large hard cervical or axillary gland tumors were the outstanding manifestation. In two cases it was difficult to distinguish the gland masses from a primary carcinoma of the thyroid until the lung examination and biopsy showed lung carcinoma. Small carcinomas of the piriform sinus, nasopharynx or accessory nasal sinuses may produce large cervical metastases, and these must be excluded in a differential diagnosis.

Hepatic Type—Here we have placed several cases presenting extensive liver metastases and great enlarge-

ment of the liver accompanied by jaundice. The jaundice is usually due to compression of the larger bile ducts or the common duct. Liver enlargement was found on physical examination in 24 per cent of all our cases. The large liver and icterus may easily lead to the diagnosis of a carcinoma of the head of the pancreas with liver metastases, or a primary malignant hepatoma when the gastro-intestinal tract is normal.

LUNG CHANGES

The physical changes vary greatly with the size and location of the tumor. In about 15 per cent of the cases there are no positive lung changes. These are the patients who present themselves because of bloody expectoration, pain or cough. Until the tumor produces stenosis of a bronchus with atelectasis or involves the peripheral lung tissue the percussion and auscultation may reveal nothing. However, the roentgen examination may be diagnostic even in the early stages.

The endobronchial form produces stenosis of a bronchus with atelectasis. There is dullness with suppressed or absent breath sounds. The chest wall is retracted with reduced mobility. The diaphragm is often elevated and the heart displaced toward the affected side. The absence of adventitious sounds speaks against tuberculosis. With partial bronchial occlusion there may be the characteristic cornage breath sounds, a peculiar type of tubular breathing.

The hilar or central form is one of the most frequent types, because many of the carcinomas originate in a main bronchus. There is often dullness or flatness on percussion to the right of the sternum or to the left of the heart. We have often found paravertebral dullness at the level of the second to fourth dorsal spines. Hard enlarged supraclavicular or axillary lymph nodes point to lung carcinoma. In the nodular type of tumor the phenomena are those of a mediastinal tumor with dullness and pressure symptoms. There is often an asthmatoïd wheeze, brassy cough, distention of the veins of the head and neck, and cyanosis. When flatness extends to the infraclavicular region with suppressed or absent breath sounds, the diagnosis is easy. A high diaphragm with paradoxical movement, a Horner syndrome, paralysis of a vocal cord or dysphagia often occurs and assists in making the correct diagnosis. The abdomen should always be carefully examined for liver enlargement or tumor masses.

The lobar form occurs most often in the upper lobes, where the diagnosis is usually easy to make. There is a peculiar flatness with increased resistance on percussion. The flatness often has a convex lower border. It extends beyond the sternum to the opposite side, because of mediastinal infiltration. This observation one of us¹ emphasized in 1930. Over the area of flatness the breath sounds are weak or absent and the auscultatory changes are minimal. Occasionally loud bronchial breathing is heard when the bronchus is not obstructed. Cornage breath sounds, flatness, bloody sputum and enlarged supraclavicular nodes are the chief characteristics of this form. In the late stage the entire lung may be involved or an extensive hemorrhagic pleural effusion may develop, with little or no cardiac displacement. Aspiration and artificial pneumothorax may be necessary to reveal the underlying lung tumor. The fluid should be examined for tumor cells.

ROENTGEN EXAMINATION

In the diagnosis of primary carcinoma of the lung the roentgen ray is an indispensable aid. Not only will it confirm the clinical diagnosis in a high percentage

of cases but it will also reveal certain cases that cannot be diagnosed in any other way. After a wide experience with numerous postmortem studies we are prepared to state that about two thirds of the cases can be diagnosed from the roentgen study alone. In the other one third a pleural effusion or empyema, pneumonia or lung abscess, marked pleural thickening, or involvement of an entire lung may make the roentgen diagnosis difficult or impossible. Even in this difficult group greater exposure of the affected side will often reveal diagnostic changes. Injection of iodized oil often discloses stenosis of a bronchus by the tumor. An enlargement, distortion and increased density of the hilar shadow on the opposite side, bone metastases, paralysis of a diaphragm, a massive effusion with little or no cardiac displacements, or lung metastases, are all x-ray aids to a correct diagnosis. In difficult cases the bronchoscope may be necessary for the final decision.

The hilar type leads to an enlarged dense hilar shadow. It is often composed of the nodular tumor, bronchial gland metastases, and lymphangitis along the blood vessels and bronchi. A branching radiary shadow invades the lung field, with increase in the size, density and number of the lung markings. The picture is so characteristic that the diagnosis is usually easy. In some cases Hodgkin's disease or lymphosarcoma may produce a similar picture, and then a biopsy of a lymph node or piece of tissue from a bronchus may be necessary for diagnosis. Often there is the picture of a lymphangitis carcinomatosa with numerous small shadows connected by a fine network. Obstruction of a bronchus leads to the picture of atelectasis with traction of the heart to the affected side, often a high diaphragm, and marked reduction in size of the lobe. The border is often sharply defined before tumor infiltration takes place. Atelectasis plays an important role in producing the early shadows of lung carcinoma.

The lobar type produces a very dense shadow. The outline at the interlobar fissure may be sharp and convex. Later it becomes irregular, with many projections into the adjacent lobe. In the upper lobe the convexity of the lower border usually distinguishes carcinoma from tuberculosis or pneumonia. The hilar markings are enlarged, sometimes with nodular tumor shadows. Soon the shadow invades the adjacent lobe, sending numerous branching strands into the lung parenchyma. The diaphragm may stand high, owing to involvement of the phrenic nerve. Iodized oil often reveals the bronchus stenosis. Bronchiectases or abscesses are frequent occurrences in the tumor or surrounding lung tissue. A long exposure of the film is often necessary to reveal them. The tumor is usually radioresistant and does not decrease much after roentgen therapy.

Table 5 gives the important clinical observations in this series of 135 cases of primary carcinoma of the lung. Further details with illustrative cases will be published later.

SUMMARY

Primary carcinoma of the lung is one of the most frequent forms of malignancy in adults. It ranks second to gastro-intestinal carcinoma and constitutes from 6 to 8 per cent of all malignant tumors. About 75 per cent of the cases occur between the ages of 40 and 60 years. In our series of 135 cases it was twelve times as frequent in males as in females.

The right upper lobe is the most common site. The tumors are all bronchogenic in origin and begin as a metaplasia of the basal epithelial cells. There are three important histologic types: (1) undifferentiated round or spindle cell, (2) adenocarcinoma and (3) squamous cell. All types have a marked tendency to produce lymphogenic and hematogenic metastases, but the squamous cell is usually less malignant than the other two types. Of seventy-four cases that came to necropsy only one presented no metastases. Eighty-eight per cent showed hilar gland metastases, 38 per cent abdominal lymph node, 40 per cent liver, 32 per cent kidney, 43 per cent suprarenal, 28 per cent bone, and 24 per cent brain metastases. The chief associated lung changes were pleural effusions (47 per cent), bronchiectases (43 per cent), acute pneumonias (28 per cent), chronic pneumonia (20 per cent), abscess or gangrene (20 per cent) and purulent bronchitis (19 per cent).

In 51 per cent of all cases the signs and symptoms were predominantly outside the lungs, only 49 per cent presented changes that were largely thoracic. This

important fact explains the present failure in most clinics to diagnose 50 per cent of the cases. In the hope of bringing the correct diagnoses to 90 per cent, where we think they ought to be, we have divided the cases into the following clinical types and discussed each: (1) pulmonary, (2) osseous, (3) cerebral, (4) cardiac, (5) gastro-intestinal, (6) lymphoglandular and (7) hepatic.

The peculiarly characteristic history of pulmonary well being to within an average period of eight months before seeking medical aid, the development of bronchitis or recurrent attacks of pneumonia or pleurisy, followed by persistent cough, pulmonary or extrapulmonary pain, hemoptysis, and dyspnea should enable the physician to suspect lung carcinoma. A characteristic complex of physical changes is observed in most cases. The roentgen study alone makes the diagnosis possible in at least two thirds of the cases. The bronchoscope is of great value in confirming the diagnosis, but most cases can be recognized without it. The presence of one of the three types of carcinoma in a biopsy specimen from a bronchus, lymph nodes, pleural exudate, or tissue found in the sputum will establish the diagnosis.

USE OF THE X-RAYS IN PULMONARY TUBERCULOSIS

FROM THE POINT OF VIEW OF PROGNOSIS

FRANCIS B. TRUDEAU, M.D.

SARANAC LAKE, N. Y.

The value of the x-rays in the diagnosis of pulmonary tuberculosis has been well established. I also feel that, without their use, one would be greatly handicapped in following the clinical course of the disease, as well as in determining the proper treatment. Besides this, I am strongly of the opinion that much valuable information can be obtained by a careful study of chest x-ray films in predicting the future trend of the disease and the patient's chance of ultimate recovery.

In this study the following points are to be considered purely in relation to their effect on prognosis: 1. Extent of disease as based on the roentgen examination. 2. Character and types of shadows. 3. Absence or presence of cavities. 4. Behavior of cavities. 5. Increase or decrease of x-ray shadows. 6. Prognostic significance of (a) fever versus x-ray shadows, (b) fever versus comparative x-ray studies, and (c) relapse versus x-ray shadows. 7. Relapse in relation to comparative x-ray studies.

In order to obtain some statistics on these various points I have selected groups of several hundred consecutive admissions to Trudeau Sanatorium, have studied the x-ray films of these patients, and then have followed the patients in each group for a period of years.

EXTENT OF DISEASE AS BASED ON THE ROENTGEN EXAMINATION

Undoubtedly, all will agree to the general supposition that the greater the lung involvement the worse the prognosis, yet I thought it might be of interest to see just what the actual figures would show. I therefore

Chart 1—Incidence of death at the end of five years in 943 cases classified on the basis of the roentgen examination. T total D dead L living

took 943 routine cases admitted to Trudeau Sanatorium within the past seven or eight years and divided them into the three usual groups as determined by the roentgen examination.

A. Minimal. Disease to the second rib and fifth vertebral spine on one side or one-half this amount on both sides.

B. Moderately advanced. Infiltration of one lung or its equivalent, consolidation of one lobe, or cavity up to 4 cm in size.

C. Far advanced. More involvement than the moderately advanced.

I then looked up their records at the end of five years. These showed that at the end of this period

only five patients, or 3 per cent, had died from among the 190 cases in the minimal group. There were ninety-six, or 15 per cent, from the 649 moderately advanced cases, while, of the 104 far advanced cases thirty-nine patients, or 39 per cent, had died. Chart 1 therefore gives some idea of a patient's prognosis at the end of five years, based purely on the amount of lung involvement as revealed by the x-ray film.

CHARACTER AND TYPES OF SHADOWS

In recent years there have come to be recognized two rather distinct types of lung shadows cast on the x-ray film, which have been interpreted as indicating equally distinctive underlying pathologic changes. The first of these has the appearance of soft, fluffy smoke, with

Chart 2—Progress of 365 cases classified according to types of x-ray shadows. T total F favorable UF unfavorable

very ill defined margins. It is felt that the disease casting this shadow is apt to be both recent and active. To this type of shadow the name "exudative" has been applied. The other type referred to is indicative of the "proliferative" lesion, which, it is felt, is of much longer duration and more fibrous in character. Here the appearance of the lesion on the film is much more clean cut and stringy, with margins well defined.

The patients in these two groups have been studied from a rather different angle than the others here reported. On entrance to the sanatorium 365 cases were classified, according to the films alone, as 243 proliferative and 122 exudative. The behavior of the lesion while the patients were with us under treatment was then watched by their subsequent roentgenograms and the results were recorded as simply "favorable" or "unfavorable." These results were indeed most enlightening, as shown by chart 2, for we found that 220, or 91 per cent, of our "proliferative" group had done well whereas only forty-seven, or 39 per cent, of our 122 "exudative" cases had made satisfactory progress. Hence the character of the shadow and its proper interpretation are of great value in determining the future course of the disease.

PRESENCE OR ABSENCE OF CAVITIES

Examination of 925 routine admissions to Trudeau Sanatorium ten or fifteen years ago reveals that cavities were read in the films of 392, or 42 per cent, of these cases. Without taking into consideration the amount of involvement in the lungs of these patients but simply the fact of a cavity being present, it is found that at the end of five years 139, or 35 per cent, are dead, while of the remaining 533 patients whose films failed to disclose the presence of a cavity only 108, or 20 per cent, had died. Thus the percentage of deaths among cavity cases was within 5 per cent of double that among noncavity cases.

BEHAVIOR OF CAVITIES

Another angle of this question, which is most important, is how these cavities behave while under treatment. I therefore followed the course of 336 patients with cavities while they were with us and found that in 122 cases or 36 per cent, the cavities remained approximately the same size. Of these patients forty-one, or 34 per cent, died within five years after leaving the sanatorium. In eighty-one cases, or 24 per cent, the cavities increased in size and this group showed forty-four, or 54 per cent, dead in five years. The films revealed that in 133, or 39 per cent, of the cases the cavities had decreased or had disappeared completely. Of these more fortunate individuals only fifteen, or 11 per cent, had succumbed during the five year period.

THE EFFECT OF INCREASE OR DECREASE OF
X-RAY SHADOWS AS DETERMINED BY
COMPARATIVE FILMS

The figures for charts 5, 6, 7, 8 and 9 are based on 600 consecutive admissions to Trudeau Sanatorium in which the patients were followed from three to five years after their discharge. They were then classified into the four groups of well, living, dead and unknown. The well group were either working or were able to do so, while the living group includes those patients who are either continuing treatment or about whom we know nothing further than that they are still living.

Chart 3—Percentage of deaths at the end of five years in 925 cases with and without cavities. T total D dead L living

Chart 5 is a comparative study of (1) those patients whose x-ray films showed a steady healing of their disease, each successive film showing either fewer pathologic shadows or, at least, that no new shadows had developed, and (2) those patients who at some time during their stay with us received an unfavorable x-ray report, stating that a comparative reading had shown an increase of infiltration or else that a previously mentioned cavity had become larger.

Fortunately, 80 per cent of the series fell into the former group and of those 72 per cent are found to be well and only 9 per cent dead. These figures are indeed striking when they are compared with the 20 per cent of patients whose films had shown a progression of their disease, for here the percentage of deaths is actually higher than that of recoveries, namely, 37 per cent dead as against 36 per cent recovered.

PROGNOSTIC SIGNIFICANCE

Of (1) *Fever versus X-Ray Shadows*—From a previous study it had been determined that from a clinical point of view the presence of fever was indicative of a graver prognosis than any other symptom or laboratory finding. I therefore thought that it might be instructive to compare the significance of this symptom with the five year outcome of patients who had shown an increase in their comparative x-ray films while they were in the institution. I found that in our series of

600 patients 168, or 28 per cent, had had fever of 99.6 F or over for five consecutive days which we were unable to account for from any other source than their tuberculosis. Analysis of these fever cases discloses that only 45 per cent of the patients are well, while 42 per cent died within five years.

As unfavorable as these figures seem to be, it is found that those patients showing a progression of their disease as determined by roentgen examination have just as serious an outlook as their fellow patients who have

Chart 4—Percentage of deaths at the end of five years in 336 cases classified as to behavior of cavities under treatment. T total D dead L living

a persistent elevation of temperature. In chart 6 the two conditions are treated independently of each other, whereas of course they are frequently found associated in the same patient. This point will be illustrated later. The most striking thing to note in this chart showing the five year results in patients having an increase in their comparative x-ray shadows is the fact that at the end of this time 1 per cent more are dead (37 per cent) than are well (36 per cent).

Of (b) *Fever versus Comparative X-Ray Studies*—Chart 7 takes up various combinations of patients with and without fever and also with and without increased x-ray shadows. The columns on the left represent sixty patients, or 9.5 per cent of our total in whom both elevation of temperature and increased x-ray shadows were noted. Among these only 23 per cent were well at the end of five years, while over twice this number, or 51 per cent, had died.

Chart 5—Increased versus decreased x-ray shadows in 600 cases followed from three to five years

The next columns to the right show that in 450 patients, or 75.5 per cent, fever was not noted during their stay with us and the x-ray shadows showed the pulmonary process either to have remained unchanged or to have improved. Under these conditions 72.5 per cent, are well with only 8 per cent of deaths.

Again moving to the right on the chart one finds sixty patients, or 10 per cent of the total, in whom no fever was present, yet the x-rays showed a progression of their disease. The "wells" immediately drop to 48 per cent and the deaths rise to 23 per cent. It is to

be noted particularly that increased x-ray shadows are found in 10 per cent of patients in whom this fact is not indicated by the presence of fever.

The series to the extreme right of this chart indicates that in only 5 per cent of patients having fever did the x-rays fail to show a progression of their disease, while

Chart 6—Fever versus increased x-ray shadows in 600 cases followed for five years. T total W well L living D dead U unknown

in this small group with fever but no unfavorable x-ray changes the well column reached 60 per cent and the deaths 20 per cent.

Of (c) Râles versus X-Ray Shadows—The next question to be considered is a comparative study of the importance from a prognostic standpoint of increased and decreased x-ray shadows versus increased and decreased physical signs (râles). Chart 8 seems to show rather clearly that progression of the disease as shown by the roentgen examination is of much graver significance than when it is indicated by physical examination. Of the patients showing an increase of this disease as determined by a larger area over which râles are heard, 55 per cent are well after five years.

Chart 7—Comparative x-ray studies versus fever in 600 cases followed for from three to five years. T total W well L living D dead U unknown

as contrasted to only 36 per cent of "wells" among those whose increase of trouble was shown by the x-ray film. The latter group shows 37 per cent of deaths as contrasted to 22 per cent of those having increased râles. It is interesting to note that there is practically no difference between the x-ray and râle groups in those patients in whom, by either of these two methods of examination, no change or an improvement in their lesions is noted.

RELAPSE IN RELATION TO COMPARATIVE X-RAY STUDIES

Chart 9 takes up the matter from a slightly different angle. Here we have followed the yearly report cards of our 600 patients and have divided them into the following groups:

1 Those whom we have classified as "cured," 53 per cent of the series, refer to those patients who left the

sanatorium in good condition and have remained "well" ever since. In this group only 11 per cent had x-ray increases while with us.

2 This class is made up of patients, 11 per cent of the series, who, although they have been "well" for the past one or two years, have had a relapse of their disease at some time during the five year period. Thirteen per cent of this group while with us had had unfavorable x-ray reports.

3 Sixteen per cent of our series after leaving us either relapsed or remained chronically ill. This result was very accurately predicted by their x-ray films, which showed a progression of their disease in 29 per cent of the cases.

Chart 8—Râles versus x-ray shadows in 600 cases followed for from three to five years

4 Among the 14 per cent in our "dead" group the "handwriting on the wall" was fairly well shown by the fact that 49 per cent of them showed unfavorable comparative x-ray films while they were still patients in the sanatorium.

5 The "unknown," or those on whom we have no follow-up record, are only 6 per cent and need no further mention.

The groups just mentioned, together with the figures quoted, are shown in chart 9.

CONCLUSIONS

The study indicates that

1 The extent of lung involvement greatly influences the prognosis in pulmonary tuberculosis, the death rate being in direct proportion to the amount of disease.

Chart 9—Incidence of relapse in relation to comparative x-ray studies in 600 cases followed for from three to five years

2 The prognosis in the "exudative" type of disease is decidedly more unfavorable than in the "proliferative" type.

3 The presence of cavities nearly doubles the probability of death within five years.

4 Cavity cases showing improvement under treatment have approximately five times as favorable prognosis as those in which the cavities become larger during sanatorium residence.

5 Patients whose comparative roentgen examinations are constantly favorable under sanatorium treatment have more than twice as good a chance of being well at the end of a five year period and only one fourth as great a chance of being dead as those who have increased x-ray shadows

6 Increase in comparative x-ray studies suggests a prognosis about equally unfavorable with that indicated by the presence of fever

7 Patients with both fever and increased x-ray shadows have six times as unfavorable an outlook as those who are free of fever and whose roentgen examinations show consistent improvement

8 Increased comparative x-ray shadows are of much graver prognostic significance than increased physical signs (râles)

9 The yearly follow-up records of 600 patients show that the relation of "well," "relapsed but now well," "chronic," and "dead" is in direct ratio to the incidence of x-ray increases while they were under our care

THE ACTUAL VALUE OF CARBON DIOXIDE-OXYGEN INHALATION

IN ACCELERATING THE REDUCTION OF TOTAL BODY ALCOHOL

HENRY NEWMAN, M.D.

AND

JOHN CARD, M.D.

SAN FRANCISCO

It has long been known that the metabolism of alcohol in the body proceeds at a constant rate for the individual,¹ and the difficulty of effecting a change in this rate has been frequently remarked.²

Robinson and Selesnick³ have recently reported striking reduction of the venous blood alcohol in inebriates who have been subjected to the inhalation of a mixture of 90 per cent oxygen and 10 per cent carbon dioxide for a period of thirty minutes. This amounted in a number of cases to approximately one fourth of the original value. They state that this is "proof of the efficacy of carbon dioxide-oxygen inhalation in causing an accelerated significant decrease in total body alcohol level," since, as they further state, "an accelerated decrease in venous blood alcohol with carbon dioxide-oxygen therapy represents an accelerated decrease in total body alcohol."

Such a striking effect certainly merited experimental investigation. The first obstacle to this was the mixed nature of the therapy, as both carbon dioxide and oxygen were employed simultaneously. Fortunately, however, Fleming and Reynolds² have investigated the effect of oxygen inhalation on the rate of disappearance of alcohol from the blood and found it to be negligible, while Barach⁴ found the lethal dose of alcohol for

rabbits to be the same in an atmosphere of oxygen as it was in air. Thus we need concern ourselves with carbon dioxide alone. As early as 1924 Hunter and Mudd⁵ administered a test dose of alcohol to a single subject on two occasions, once with and once without inhalation of carbon dioxide. They interpret their results to indicate that the reduction of blood alcohol proceeds more rapidly when carbon dioxide is administered, but this interpretation is not agreed to by Fleming and Reynolds,² who found no effect from inhalation of either carbon dioxide or oxygen.

Since the absence of reduction of blood alcohol in some of the cases reported by Robinson and Selesnick is ascribed by them to the possibility that further absorption from the gastro-intestinal tract took place, we determined to obviate this chance for error by administering the alcohol intravenously. To each of two human subjects a dose of 2 cc of ethyl alcohol per kilogram of body weight was administered intravenously, as a 20 per cent solution in physiologic solution of sodium chloride, the injection taking one hour. An hour was allowed to elapse for equilibration of the alcohol between the blood and tissues, at the end of which time the first blood sample was taken. After another hour a second blood sample was taken, the minute volume of respiration determined with a spirometer, and inhalation of carbon dioxide 10 per cent and oxygen 90 per cent begun, an open slot mask being used, so that no rebreathing occurred. This was continued for thirty minutes, during which time the respiratory minute volume was twice determined and blood samples were taken. After the inhalation period blood samples were again obtained at appropriate intervals. The alcohol content of all the samples was determined by a modification of the method of Cannan and Sulzer.⁶ The curve of the blood alcohol in one of these subjects is seen in the accompanying chart. It will be noted that the rate of fall of the blood alcohol significantly increases during the period of inhalation.

Change in the Rate of Decrease of Venous Blood Alcohol Effected by Inhalation of Carbon Dioxide-Oxygen Mixture After a Dose of Alcohol of 4 Cc per Kilogram Intravenously in Dogs

Animal	Maximum Blood Alcohol Mg per 100 Cc	Before Inhalation	Rate of Decrease of Blood Alcohol in Mg per 100 Cc per Hour			
			During Inhalation	1/4 Hr after Inhalation	1 1/2 Hrs after Inhalation	
1	351	22	34	6	19	
2	372	23	20	2	24	
3	370	18	48	6	18	

but that on its discontinuance a rise occurs, followed by a period of slower fall, and finally a rate comparable to that before the inhalation was begun.

To confirm these results with higher doses, giving blood alcohol levels comparable to those of the inebriates reported by Robinson and Selesnick, the same procedure was repeated, using dogs, with a dose twice that given to the human subjects, namely, 4 cc per kilogram. This was sufficient in all cases to produce a state of coma from which the animals could not be aroused. It is of interest from the clinical point of view, with which we are not here specifically concerned, that none of the dogs were any more easily aroused after the carbon

dioxide-oxygen inhalation than before. The results of the procedure in the three dogs used are given in the accompanying table, in which it may be seen that in each case the increased rate of decline of blood alcohol is followed by a period in which there is little if any fall, after which the rate again returns to one comparable to that before inhalation was begun.

Curve of blood alcohol against time after the injection of 2 cc of ethyl alcohol per kilogram in man showing increased rate of fall during carbon dioxide oxygen inhalation with compensatory rise following

The significant fact obtained from this experimentation is that there is no actually significant change in the rate of decrease of total body alcohol brought about by the inhalation of the carbon dioxide-oxygen mixture for a period of a half hour. True, there is an acceleration of the decrease of venous blood alcohol during the period of inhalation, but this is compensated for by a subsequent period during which the blood alcohol declines slowly or even rises, so that the fundamental rate of decrease is not appreciably affected. The explanation of this is simple. During the period of inhalation there is, to be sure, an increase in the amount of alcohol eliminated in the breath, which measurably decreases the amount of alcohol in the blood-stream, accounting for the more rapid decrease in blood alcohol observed. This decrease is not, however, immediately participated in by the tissues, which hold the great bulk of the total body alcohol, since it has been shown that a considerable period is required for equilibration of alcohol between the blood and the body tissues.⁷ Subsequently, when the respiratory elimination has fallen to normal after the inhalation has been discontinued, equilibrium is again established by movement of alcohol from the tissues into the alcohol-depleted blood, accounting for the period of decreased rate of fall or even rise of blood alcohol.

The fact remains that in order for even the blood, if not the body tissue, alcohol to accelerate its rate of decline there must be some increased elimination of alcohol through the lungs. An accurate appraisal of the magnitude of this increase may be arrived at if one knows the alcohol content of the expired air and its volume. The minute volume of respiration in our two human subjects changed, on an average for the two, from 6.5 liters to 35.5 liters, or over fivefold. This is an increase of 29 liters per minute, or 870 liters for

the half-hour period of the inhalation. Now it has been shown that a liter of expired air contains from one fourth to one half as much alcohol as a cubic centimeter of blood taken at the same time.⁸ The average blood alcohol value in our subjects over the period of inhalation was 1.6 mg per hundred cubic centimeters, so that the content of their breath must have been from 0.4 to 0.8 mg per liter. Multiplying the higher figure by the number of liters of increased respiration during the inhalation period gives 0.696 Gm of alcohol as the amount by which the total body alcohol has been reduced by the treatment. When one considers that this is less than 1 per cent of the total body alcohol at that time, it is readily seen that the decrease could hardly be called significant.

It is not our purpose in this paper to discuss the efficacy of such a mixture of gases in effecting clinical improvement in cases of severe alcoholic intoxication, in which much of the danger lies in depression of the medullary centers, among them the respiratory center, which is subject to stimulation by carbon dioxide. Indeed, there may be even other factors operating, as evidence the remarkable effect of carbon dioxide inhalation in catatonic stupor. Nevertheless, it has been conclusively shown that whatever improvement takes place cannot be accounted for by a reduction of total body alcohol, reduction of venous blood alcohol notwithstanding.

CONCLUSION

The inhalation of carbon dioxide 10 per cent and oxygen 90 per cent for a period of thirty minutes is not effective in significantly reducing the total body alcohol.

EXTRANEOUS SHADOWS COMPLICATING UROGRAPHY

WITH SPECIAL REFERENCE TO RADIOPAQUE PILLS

ADOLPH HARTUNG, MD

AND

T. J. WACHOWSKI, MD

CHICAGO

The roentgen diagnosis of intra-abdominal pathologic conditions is difficult largely because of the many organs contained within the abdomen. When their shadows can be distinguished, the single roentgenogram necessarily presents them with more or less overlapping of outlines. If the pathologic process suspected expresses itself in calcifications, it is often difficult to localize these as being in a particular organ.

This situation is especially trying in urologic conditions, in which concretions play a leading role and the area traversed by the involved tract is extensive. While urinary concretions may be fairly characteristic, they are not always so and may be hard to differentiate from calcifications in nearby structures. Also, there may occur extraneous densities, of more or less accidental origin, to confuse the picture further.

From the fairly extensive literature on the subject, Holmes and Ruggles¹ have gathered the following list of densities that may simulate renal concretions.¹

⁸ Haggard and Greenberg.⁷ Smith, Sydney, and Stewart, C. P. Diagnosis of Drunkenness from the Excretion of Alcohol. *Brit. M. J.* 1: 87 (Jan. 16) 1932.

Increased density of the tip of a transverse process 8 Small areas of density in the spleen 9 Calcification in a blood clot or surrounding a foreign body (including the ever troublesome phlebolith) 10 Shadows from fibromas, scars or dressings 11 Artefacts present in the film or screen

Case² calls attention to the shadows cast by warts, and Young³ found that articles of clothing coming into the field may be confusing

Within the last two years at the University of Illinois Research and Educational Hospitals, we have seen a number of urologic cases presenting localized dense shadows which shifted disappeared and reappeared in a startling manner

CASE 1—One of the first and most vexing cases was that of H. R. a woman aged 28 who entered the hospital Feb 15, 1934. She had had a right-sided pyelitis performed in 1931, which had cleared up quickly, and there had been no exacerbation during a subsequent full term pregnancy

Six weeks prior to her admission to the hospital she had suffered a chill followed by a fever up to 104 F and had developed an aching sensation in the right loin, present only when standing. There was no radiation of the pain and only slight kidney tenderness. There was no dysuria nor frequency, although some pus was found in the urine. She had had an appendectomy and right oophorectomy

The plain film of the urinary tract showed a localized round dense shadow to the left of the second lumbar vertebra and an oval one to the right at the same level. A right-sided retrograde pyelogram was attempted. The film showed no densities. The right ureteral catheter curved back opposite the second lumbar vertebra and the opaque solution ran into the bladder. A subsequent intravenous pyelogram showed a right-sided

pyelectasis. On the left side there was distortion of the pelvic outline and an apparent filling irregularity with two localized accumulations of what was taken to be opaque urine in the parenchymal region. The observations were considered consistent with a pyelectasis of the right side and a pyonephritis on the left side. Two days later a left-sided retrograde pyelogram was made and again the two localized densities were seen on that side. The outlined left kidney pelvis, however, showed only questionable dilatation and the opaque fluid did not extend to the localized densities (fig 1). Exploration of the right kidney showed a localized mass in the upper pole and a kink at the ureteropelvic junction. Sections of a biopsy specimen showed what looked like an old infarct or carbuncle.

CASE 2—Soon afterward we examined C. H., a boy, aged 4, who had been under treatment at the hospital several months for a Pott's disease of the third lumbar vertebra. He was sent to us with the history of a recurrent B. coli urinary infection of several months duration. Recently organisms suspected of being tubercle bacilli had been found in the urine. The films taken after the injection of skiodan showed a localized density superimposed on the twelfth rib on the right side which had to be considered as a possible calculus. On the left side were seen two round dense shadows at about the level of the twelfth dorsal vertebra, of doubtful origin. Check-up films showed no dense shadows, but they reappeared at a subsequent examination.

CASE 3—J. S., a woman, aged 51, was referred for a film of the urinary tract because of pain on the right side. The film taken

(fig 3) showed two radiodensities in the left kidney region which may have represented urinary concretions. A second film (fig 4) was taken a few minutes later for a technical experiment and to our surprise this film failed to show the presence of any densities.

Questioning brought forth the information that the patient had ingested several enteric coated ammonium chloride pills shortly before the first film was taken.

Fig 3 (case 3)—Left kidney area showing localized densities that simulate concretions

Fig 4 (case 3)—Left kidney area a few minutes later (film taken for technical experiment) densities no longer visible

The similarity of the appearance and behavior of the shadows seen in these and other cases led to a review of their medical management for a possible explanation of their source.

The only medicinal agents that the patients who were examined had been receiving were ammonium chloride and sodium acid phosphate, drugs which in recent years have become the usual means of influencing the pH

2 Case J. T. Am. J. Roentgenol. 3: 333 (June) 1916.
3 Young J. S. J. Missouri M. A. 13: 502 (Oct) 1916.

of the urine.⁴ Under fluoroscopic guidance, therefore we administered pills of these substances to the second patient and were surprised to note the dense shadow cast by the ammonium chloride (fig 2). The sodium acid phosphate was faintly visible and then faded while still in the stomach. The ammonium chloride, being enteric coated, maintained its density while in the stomach and often took many hours to dissolve after passing the pylorus. Recently, Bukey and Drew⁵ have shown that the average emptying time of enteric coated pills from the stomach is almost six hours, although most of them pass out in four hours. The dissolving time of the coating depends on its composition and thickness and some coatings are so efficient as to pass through the entire digestive tract undissolved.⁶ Thus while traversing the alimentary canal it may several

certain substances are combined the resulting density is not always what one would expect by simply adding the absorption indexes of the two substances. This variation may be in either direction and conforms to our experience.

With a view toward determining the absorptive capacity of other pills, we took at random thirty-three pills and tablets of the commonly used drugs and exposed them alongside a graduated aluminum scale to observe their relative densities (fig 5). It will be noted that sodium bromide, 10 grains (0.65 Gm.), and triple bromide, 15 grains (1 Gm.), 8 and 9 respectively in the top row, are the densest. Menville found their shadows much denser than their rating according to formula. Using Menville's figures, which are based on beryllium as 1 the density rating of ammonium

Fig 5—Row 1 1 Ammonium chloride 5 grains (0.3 Gm.) no coating 2 Ammonium chloride 7½ grains (0.5 Gm.) enteric coated 3 Acetphenetidin 5 grains 4 Acetylsalicylic acid 5 grains 5 Mass of ferrous carbonate 5 grains 6 Sodium bicarbonate 5 grains 7 Sodium bicarbonate 10 grains (0.65 Gm.) 8 Sodium bromide 10 grains 9 Triple bromide 15 grains (1 Gm.) 10 Compound cathartic enteric coated 11 Calcium lactate 5 grains 12 Calcium lactate 10 grains Row 2 1 Extract of cascara 5 grains 2 Cinchophen 5 grains 3 Cinchophen 7½ grains 4 Digitolin 5 grains 5 Neocinchophen 5 grains 6 Methenamine 5 grains sodium acid phosphate 5 grains 7 Methenamine 5 grains 8 Methenamine 5 grains sodium acid phosphate 5 grains 9 Nephritin 5 grains 10 Glyceril trinitrate 1½ grains (0.0004 Gm.) 11 Ovarian extract 5 grains 12 Ovarian extract 2 grains Row 3 1 Ovarian extract corpus luteum extract thyroid extract 2 Parathyroid extract 1½ grains (0.006 Gm.) 3 Phenobarbital ¼ grain (0.016 Gm.) 4 Phenobarbital 1½ grains (0.1 Gm.) 5 Phenolphthalein 1 grain (0.065 Gm.) 6 Sodium acid phosphate 5 grains 7 Sodium acid phosphate 10 grains 8 Aminopyrine 5 grains 9 Sodium salicylate 10 grains 10 Thyroid extract 2 grains. The graduated scale at the top consists of twenty steps of aluminum each step being 1 mm thick.

times be in a position where it would be superimposed on the urinary tract.

Hull⁷ has outlined the fundamentals that govern the roentgen absorptive power of any substance and has evolved a formula to determine the amount of such absorption. Briefly stated this absorption or shadowing is about in proportion to the cube of the atomic number of the substance multiplied by its density. Menville⁸ working with metallic salts, found however, that when

chloride, 5 grains (0.3 Gm.), uncoated, 1 in the first row, is 64.98. Its shadow is denser however, than that of 6 in the third row, sodium biphosphate, 5 grains, the rating of which is 102.31. The shadow of ammonium chloride, 7½ grains (0.5 Gm.), enteric coated, 2 in the first row is disproportionately dense even in comparison with the smaller uncoated tablet next to it. This is probably because the enteric coating on this pill consists mainly of a resin to which is added a certain amount of calcium carbonate a rather radiopaque substance. Its density will also be seen to be much greater than that of pill of ferrous carbonate, 5 grains 5 in the first row, which has been often quoted as a confusing shadow.

THE RADIOLOGIC INVESTIGATION OF
THE SUPERIOR MAXILLARY
ANTRUME. H. SHANNON, M.D.
Radiologist St. Michael's Hospital
TORONTO, ONT.

Since the advent of iodized poppy-seed oil little of value has been added to our knowledge of diseases of the accessory nasal sinuses to facilitate radiographic diagnosis. The trend in many quarters has been away from the use of so-called plain x-ray films in favor of the employment of opaque mediums. While holding no brief for either method to the exclusion of the other, I believe that the time may be opportune for a survey of the major diagnostic criteria afforded by plain sinus films. An estimate of the accuracy of the method is attempted as checked by the results in 296 patients on whom the radical antrum operation has recently been performed.

The frequency of infection of the maxillary antrums in sinus disease—variously estimated as occurring in from 75 to 90 per cent of all sinus infections, and the difficulty that may exist in its clinical demonstration in chronic forms—lends to the radiologic examination of the antrums a special importance. Infection of the antrum may be sufficiently obvious at clinical examination and may require only confirmation or evidence as to character and extent. It is, however, a matter of everyday observation that so-called chronic maxillary sinusitis or even repeated subacute infections may fail to cause local symptoms and may remain unsuspected, even though productive of systemic disturbances from direct absorption of toxins or by secondary infections in the joints, the chest or elsewhere. There may be no nasal discharge, though postnasal dropping and repeated head colds are the usual accompaniments of the disease. Transillumination, as has been definitely proved, may be negative even in the presence of an antrum full of mucoid material or polyps. This phenomenon is apparently due to the ability of certain substances to refract light normally. Indeed the antrum may be more brightly illuminated on the diseased than on the normal side, probably because of coincident decalcification of its walls. Further an old healed infection cannot be distinguished by transillumination from one that is recent and active.

Pathologic processes of inflammatory type within the antrum manifest themselves in several ways: by production of pus, by thickening of the mucoperiosteum by polypoid degeneration or cyst formation and by reactive changes in the bony walls. These processes may be identified with considerable accuracy in "plain" x-ray films. The use of iodized oils is rarely necessary and may completely obscure a valuable indication of disease: the condensing osteitis seen in cases of chronic suppuration and the rarefying type commonly associated with chronic polypoid degeneration of the mucous membrane.

The radiologic examination of the maxillary antrum is seldom necessary in the presence of an acute infection. Intrinsically there is a slight decrease in brilliance of all the sinuses, often occurring first in the ethmoidal cells in appearance much like that seen in allergic individuals in the ragweed season. Such an acute infection may clear up with little or no residual change

or may go on to pus formation. In the latter event if drainage is free one may find only a thickened mucous membrane. The thickening may be such as to be barely visible or may almost entirely fill the antrum cavity. The normal mucous membrane, it will be recalled, is not demonstrable in a roentgenogram. If drainage is completely blocked an empyema of the antrum occurs, and a more or less uniformly dense shadow is produced which almost obliterates the superimposed skull markings, as the shadow of the foramen rotundum and the sphenoidal fissure. If drainage is incomplete or is accomplished intermittently by blowing the nose or by postural means, the antrum may be partially filled with exudate, with air overlying. On examination of the patient in the prone position a diffuse haziness is seen and the radiologist may find it difficult to differentiate between pus and polyps. The distinction may sometimes be made with certainty by examination in the erect position, in which a fluid surface, usually concave superiorly, and with air above may be visible. When the pus is tenacious and small in quantity or when both pus and polyps are present a fluid line may be absent, but an increased cloudiness in the region of the inferior angle will be observed in many cases when films made in the prone position are compared with others made in the erect. Even when the prone position is used, however, reactive changes in the antral walls should provide a clue as to the presence of pus. A slight increase of bone density is evident even early in the development of empyema and before the actual osteitic condensation of the chronic infection has occurred, as the result of congestion in the vascular and lymph channels and marrow spaces. Furthermore, one must at times rely on its presence as the sole means of differentiating between empyema and retention cyst entirely filling the sinus, or between an antrum containing polyps and one that harbors both polyps and pus. In chronic suppuration the marked degree of condensing osteitis is typical of the condition. It involves the walls of the antrum which are thickened by new bone formation, with inflammatory reaction often apparent also in the malar bone and floor of the orbit. In some cases of chronic suppurative pansinusitis the orbit may be the seat of a condensing osteitis and may appear actually chalky in a roentgenogram without there being any clinical evidence of an inflammatory process in the soft tissues of the orbit. The amount of bony reaction in the antral walls may quite obliterate their outline in a roentgenogram. The location of the reaction in bone is proved both by the fact that it often spreads beyond the actual limits of the antrum and by the observation that little decrease in density follows until long after removal of the contained pus or mucous membrane. At operation the bone is hard and pitted the mucoperiosteum is often adherent and the bone bleeds more than is usual.

After drainage has been accomplished in cases of empyema of the antrums the exact thickness of the mucous membrane may be seen by contrast with the admitted air. While the point is questioned by some observers I believe that the recognition of even slight mucous membrane thickening over all or part of the antrum may be most important in the search for focal infection when the antrum is seen in a quiescent period between recurring attacks. Mucosal thickening is perhaps most easily demonstrated along the antro-nasal wall which is seen almost in contour in postero-anterior films. The outer angle and posterior wall of the maxillary antrum are seen to good advantage in the nasal projection, which in many instances also pro-

vides an excellent demonstration of partitions within the antrum. Such partitions may, if complete, produce what is in effect a double cavity, one or both divisions of which may be infected. The septums usually extend from side to side but may run ventrodorsally, producing an inner and an outer division.

Localized areas of hyperplasia may be detected, occurring frequently in or close to the superior angle. A triangular shadow often occupies this angle in the

Fig 1—Small root fragment thrust into the antrum cavity during curettage of tooth socket resulting in a maxillary sinus suppurate.

Infections of dental origin have been observed to occur most frequently in the wake of tooth extraction with curettage of the socket and consequent removal of the protective zone of inflammatory reaction around infected roots, resulting in spread of the infection to the antrum. At times also the antrum floor is actually perforated by the curet and infected material thrust within. Figure 1 shows a root fragment which gained access to the antrum in that way. The pus formed in such cases is of a peculiar foul character which may be identified by the rhinologist at the time of antrum puncture.

Polypoid or cystic change results in mottled or homogeneous decrease in brilliancy producing a dull slate-like image of the diseased area, yet with normal bone detail elsewhere. Such conditions may be differentiated from suppurative processes, as previously remarked, by lack of productive reaction in bone. They do, on the contrary, produce a rarefying osteitis unless accompanied by a chronic suppuration. Polyps and cysts may be outlined most often toward the floor.

ARTEFACTS

Extraneous shadows superimposed on that of the antrum may give rise to errors of diagnosis. They may be caused by bony structures or soft tissues. Not uncommonly, inequalities of density in the superimposed shadow of the occipital bone will produce cloudiness of one side which, however, may change in appearance in the nose-chin and nose-forehead positions and can in any event be identified by stereoscopic study. At times a small asymmetrically developed antrum is seen with dense walls, which may be recognized as anatomically thick by lack of osteitic reaction in the adjacent structures, though the condition is usually apparent

nose-chin position, simulating regional hypertrophy. It is due to the shadow of the soft tissues of the nose. Localized mucous membrane thickening over the floor or more widespread changes are sometimes seen to be associated with infections at the apexes of such teeth as may lie beneath the antrum floor, the most constantly related teeth being the molars. When the antrum is small, the first molar may be omitted from the relationship.

An appearance suggesting heaping up of the mucous periosteum may be observed at the floor of the antrum in postero-anterior films in patients having unerupted teeth in the distal part of the upper jaw. Other shadows, such as those produced by the petrous bone in poorly made films, need scarcely be mentioned here.

A more deceptive appearance is sometimes caused by an outward bulging of the antronasal wall, which at times may simulate mucosal thickening.

Soft tissue shadows, which may resemble mucosal hyperplasias, may be caused by thick lips, producing a faint crescentic density inferiorly, or by broadening of the soft structures of the nose from pressure in the Waters position, causing a small triangular shadow in the superior angle.

Of far greater importance, however, is faulty technic, which may give rise to misleading appearances with burning out of mucous membrane and other detail in dense contrasty films, while in underexposed roentgenograms the bony walls tend to obscure the lighter shadows.

It may be in order at this point to observe that not every apparent error reported by the rhinologist is actual. It may require only one blowing of the nose to empty an antrum of pus, while the factor of time must also be taken into account. Mucosal thickening of 4 mm has been seen in the antrum of an allergic patient, while on reexamination, ten days later, the lining membrane was barely visible. The reverse may also occur, and in either case a surgical procedure based only on such evidence, without adequate clinical investigation, is apt to prove disconcerting. A somewhat similar experience has at times been reported when a cyst has been ruptured during antrum irrigation. Such structures may be readily mistaken for and reported as polyps, and their absence subsequently at operation may be mystifying to a degree. The demonstration of chronicity in a lesion therefore, as indicated by multiple polyps or more particularly by rarefying or condensing osteitis, is the sole guaranty that the condition found by the surgeon will be essentially that described by the radiologist.

Malignant neoplasms involving the antrum may infrequently originate in the bony walls but are usually found to be carcinomas arising from the mucous membrane. Their differential diagnosis is of course usually impossible radiologically and even the diagnosis of malignancy is difficult or impossible in the early stages on account of the suppurative process which is an almost constant accompaniment of the disease at the stage at which the patient is usually seen. In favorable cases stereoscopic study in two directions may establish the diagnosis especially in my experience, if

Fig 2—Overgrowth of bone involving the walls of the maxillary antrum showing microscopically structure reported as osteomatous in character.

the antroanasal wall is involved. It has been found that inferosuperior or supero-inferior projections have been definitely helpful. At times the neoplasm, after eroding the nasal wall of the antrum, will occupy the nasal space and while eroding the bony septum will cause pressure on it with resulting displacement.

Benign overgrowth of bone of osteomitic character is occasionally encountered. Sometimes, as illustrated in figure 2, the hyperplasia extends over an area of such size as to suggest Paget's disease in which, however, more detailed bone study usually shows the variations of texture often with small islets of condensation, typical of the disease. Dental films of the alveolar process may be found of definite value.

Omission of mention of the postoperative appearance of the antrum has been intentional. The intense reaction set up by radical operative procedures entirely masks the antrum cavity and contents, closely resembling the condensing osteitis of chronic suppuration though at times presenting a more marbled effect. The clinical record, which should accompany each patient referred for roentgen examination, should indicate the nature and date of any operative procedures that may have been carried out.

CORRELATION OF ROENTGEN AND OPERATIVE OBSERVATIONS

In 130 cases, chronic maxillary sinusitis with more or less well marked mucosal thickening was the major finding reported. In 127 cases the diagnosis was confirmed. In eighteen cases of the 127, polyps of small size were found at operation which had not been seen roentgenographically. Three cases considered acute by roentgen examination were found to be of chronic type.

Of 106 cases polypoid degeneration was reported as the outstanding feature and with subsequent operative confirmation. Four antrums in which polyps were reported were found to contain cysts. Of the 102 remaining, in two instances pus was reported to be present in quantity and was not evident to the surgeon, in four pus in quantity was found and had not been reported, in two cases polyps of a centimeter or more in diameter were removed when only mucosal thickenings had been reported.

Thirty-eight cases were described as showing evidence of barely demonstrable osteitic reaction, with no definite mucosal thickening, pus or polyps present. They were considered as representing residual changes from an old infection not active at the time of examination.

Of this group six contained one or more very small polyps not visible preoperatively or on reexamination of the films.

In twenty-two cases, frank empyema was reported and confirmed at operation. Of these, ten were reported by the surgeon to have contained polyps, the presence of which was entirely masked in the roentgenograms by the contained pus.

The difficulties in the way of an estimate of accuracy of this kind are appreciated. The various groups overlap while osteitic reaction of various degrees runs through the entire series. The presence of small amounts of pus was also a frequent finding. Further, errors made on the side of missed lesions are less apt to be uncovered the surgeon being doubtless sometimes deterred from operation by reason of a negative roentgen report. Nevertheless a survey of the tabulated results of these cases indicates that the radiologic diagnosis of chronic maxillary sinusitis made on "plain" films was essentially correct in almost every

instance. I believe that the presence of polyps in an antrum containing definite mucosal thickening, especially if an osteitic reaction is present, does not materially alter the clinical conduct of the case. In the thirty-eight cases of the 296 described as representing the end result of an old healed infection this may not apply. They form the borderline group, and it will be seen that, while definite evidence of disease was not lacking, a detailed description of the pathologic changes present was not accurate in six of thirty-eight antrums examined. In this group only a slight haziness was observed radiologically over the suspected antrum, with no definite pus or polyp formation evident. The periosteum in several instances was apparently thickened while at operation the mucous membrane was found to be adherent, the bone bled readily and was hard to the curet. I feel that the knowledge of the presence of even slight polypoid degeneration of the mucosa might influence treatment in such cases as indicating the probability of reinfection when healing was considered to have occurred. At present, therefore, I am studying the ethmoidal cells closely for a clue as to similar change occurring in that area, where it is more readily demonstrable. I believe that if doubt still exists an opaque medium may well be used to fill the antrum, by whatever method is preferred by the operator. The preliminary plain films will then establish the presence of minimal osteitic reaction, the iodized oil may reveal the slight associated polypoid degeneration of the mucous membrane.

ABSTRACT OF DISCUSSION

DR. FREDERICK M. LAW, New York. I have just returned from a large gathering of otorhinologists in Toronto. In talking with these doctors I found a great number of well known men who do not rely on interpretations of roentgenograms of the sinuses. It has been about thirteen years since attention was first called to the changes in the bony walls as a means for diagnosis but it is surprising how many reports are submitted to me in which the diagnosis is made simply on the opacity or cloudiness of the sinuses, and there the reports end. This is the kind of report which those doubting Thomases have received. It does not contain the information the surgeon desires. What he wants to know is the character of the contents of the sinuses, the quality of the bony walls and what are the anatomic difficulties which he may encounter in operating. These are facts which are evident when one looks at a perfectly made set of sinus films. Just as Dr. Shannon has pointed out there is a definite change in the characteristics of the bony walls of the sinuses in which disease exists, and the omission of such information can be laid to carelessness or ignorance on the part of the interpreter. There are technical errors of which the rhinologist is not aware and with which radiologists are familiar, thus showing the absolute necessity of cooperation and consultation. Allergy produces the greatest difficulty. As demonstrated in a case recently a relative of mine is peculiarly allergic to watermelon. I made a set of sinus roentgenograms and they were perfectly clear. Then I gave her a piece of watermelon and in thirty minutes made another set which were four plus positive sinuses. This shows the necessity for a history. If one would refuse to make a roentgenogram until one has the clinical data that error might be minimized.

Not Necessarily Spinach—Please note that green vegetables need not mean spinach. Spinach is by no means in a class by itself as a vegetable rich in vitamin A value. In tests thus far available escarole, kale and parsley have shown higher vitamin A values than spinach; other dark green leaf vegetables such as beet greens, chard, dandelion and turnip tops rank about with spinach in this respect. (It is time for the science of nutrition to throw off the incubus of too close an identification with spinach!)—Sherman, H. C. *Food and Health*. New York: Macmillan Company, 1934.

INTRAVENOUS AND RETROGRADE UROGRAPHY

A COMPARATIVE STUDY

R. E. CUMMING, M.D.

AND

G. E. CHITTENDEN, M.D.

DETROIT

Urology stands on two sturdy supporting limbs the instruments for precise visual diagnosis, of which the cystoscope is the foundation stone and urography. Because of accuracy in diagnosis and the controlling power throughout the course of most maladies of the urinary tract, afforded by their regular adaptation, an unpretentious specialty has risen to a very high plane in little more than one human generation. Nearly thirty years ago, the roentgen ray was made immeasurably valuable in the study of urogenital lesions by the successful practice of pyelography, while prior to that time some of the most spectacular films or plates for public and professional demonstration of the virtues and possibilities of the x-rays were those depicting images of stone in the urinary tract.

Lower and Nichols¹ state that perhaps in no other field of medicine and surgery has the roentgenogram been of more signal value than in the diagnosis of diseases of the urinary tract but that nevertheless it is absolutely essential for the clinical diagnosis and the roentgen examination to be considered together in any given case. As pointed out by Young and Waters,² the work of the cystoscopist was expanded greatly following the regular adoption of pyelographic technic. So likewise an added burden was placed on the roentgenologist, who was forced to learn much of the intimacies of urology in order to be of the greatest assistance possible in the interpretation of plates. The enormous amount of clinical material evaluated by Braasch³ in the compilation and revision of his work, together with atlases published in conjunction with case histories by the authors already mentioned and others has proved of equal and inestimable value to the cystoscopist and the roentgenologist.⁴ The common practice of publishing roentgenographic prints in textbooks on urology and in many articles on urologic subjects has provided a further wealth of material for all observers.

Since medical progress breeds dissatisfaction with methods at hand, the early solutions for use in filling the lumens of the urinary tract to produce radiopacity have been discarded in favor of several which are less expensive, less toxic and less irritative allowing better images, and which at present seem to answer all requirements for perfect retrograde mediums. It is interesting that the most acceptable medium today is one of those used for intravenous urography. There have been healthy improvements therefore, in the method of retrograde urography, another being the frequent use of some pyeloscopic routine. One obvious difference exists in the application of the two methods. Cystoscopic technic and skill are required for one while any

one having access to an x-ray machine can practice the other after a fashion. Therein lies a real danger in intravenous urography, and one aspect of it is the procrastination in serious illness, bred of faulty interpretations.

The development of intravenous urography has again increased the scope of work on the part of both the urologist and the roentgenologist. Taking advantage of urine secretion and adapting urine-bearing drugs to delineate the lumens of the urinary tract, a number of scientists have provided this ingenious method for physiologic investigation and diagnostic study so that now, by dint of research and painstaking application, intravenous urography has been accorded an established role in medical diagnosis. For a time, however it threatened the older method used for roentgenographic study of the kidney and ureter, retrograde urography. Its usurpation was like that of a new toy, and its use rather indiscriminate, it is still depended on by many workers to a degree that we think is absolutely unwarranted.

Without the distinct advantages of the intravenous method, the true motor physiology of the urinary tract cannot be investigated and even in its present high state of efficiency it leaves much to be desired. The ideal

Fig. 1 (case 1)—Subacute right pyelonephritis. Preliminary intravenous urography not productive of any information. Retrograde urography with catheterization of ureters and with catheter in lower pelvis of double kidney (right) readily demonstrated entire anatomic situation.

medium will be one which will so completely and suddenly suffuse the urine that pyeloscopic and serial roentgenographic studies may be regularly made and repeated on individual subjects, with certainty as to clear and complete delineation of the entire lumen including the minor renal calices and the full extent of the ureters. It is impossible to relate the experiences of those who have published hundreds of articles on the subject of intravenous urography in our own and the foreign literature. All are familiar with the valuable investigations made with the Jarre Ci-nex camera and it has been a great privilege to collaborate with Jarre in all his urographic studies. An excellent summary dealing with the general aspects of intravenous uro-

raphy and prepared by one of the pioneer workers in the field is that by Swick.⁶

One may safely predict that the final perfection of mediums for intravenous administration will allow complete visualization of all normal lumens of the urinary tract, thus enabling a final evaluation of physiology in its bearing on the normal movement of the urinary

clinical cases. The accompanying tables contain an accurate summing up of the personal opinions of a great many outstanding men. While the majority of these are urologists, a considerable list of roentgenologists appears in our file of answered questionnaires and a survey of the opinions of a number of pathologists made as a separate investigation has furnished the background for conclusions representative of the three groups mentioned.

The inaccuracies current in the practice of retrograde urography are well known, especially to experienced clinicians who are best able, on the other hand, to interpret the many variations in roentgenograms obtained by the intravenous method. Some roentgenologists seem

TABLE 1—Estimated Cases with Intravenous Method

willing to attempt a complete diagnosis of disorders of the urinary tract without the counsel of a clinician. With the two methods of urography in constant and indiscriminate use, it is more than ever necessary to establish a proper alliance between roentgenologists and clinical urologists. The correct balance allows primary choice of either method with a willingness to seek confirmation by means of the other. Many individual problems can be solved by one method, in some situations only one can be used. Taking advantage of both

Fig. 2 (case 2)—Bilateral pyelonephritis, bilateral ureteritis and bilateral ureteroceles. It was impossible to catheterize the ureters on three occasions, one with spinal anesthesia. With the catheter in the left ureteral orifice an attempt was made to obtain a ureteropyelogram. Intravenous urography readily produced images showing the entire renal pelvis, ureters and bladder. Note also peculiar deformity of bladder due to ureteroceles.

stream. Such mediums will not be universally diagnostic, however, since deviations in renal and ureteral motor function must of necessity be expected to interfere with proper filling of the lumens. Total or radical renal failure likewise will continue to allow instances of incomplete image production or entire lack of opaque shadows. Perhaps the correct dictum for the present is to the effect that the more normal the kidney and ureter, the less complete are the images obtained, barring radical dysfunction. This statement will not be accepted by many, yet we are convinced that it is true. The very fact that some men adopt special methods for preparation of patients and added details in the progress of an investigation, such as the regular use of low abdominal compression, while others strictly avoid preparation and assert that only one exposure is regularly necessary for a diagnosis, eliminating even a plain preliminary film, points to a wide variation in opinion and proves the continued transition in progress as regards the actual practice of the intravenous method.

It is our purpose to compile an up-to-date estimate of the value of intravenous urography, making comparisons with the well established method of cystoscopy (retrograde) urography and treating the subject from the standpoint of three groups, namely, roentgenologists, urologists and pathologists. To that end we prepared a questionnaire which was mailed to more than 350 active physicians. We are indebted to them for their excellent cooperation in their returns, which we are sure provide a fair cross-section of belief and experience based on the study of many thousands of

Fig. 3 (case 3)—Left ureteroceles with abnormal placement of ureteral orifice and ureteritis in ureter leading to upper pelvis of a double kidney. Repeated cystoscopy and retrograde urography failed to disclose entire pathologic condition but provided an excellent study of the lower pelvis on the left side. Intravenous urography gave an excellent demonstration of the upper pelvis and the entire ureter therefrom, demonstrating very clearly the dilatation and anomalous position of its lower segment.

and adding the regular practice of multiple or serial exposures at carefully chosen intervals, one may obtain maximum information. Well known dangers of retrograde urography, which formerly were ignored or accepted as unavoidable, are now largely eliminated, so

that justifiable fears as to potential renal damage and extension of infection no longer exist. We have found no evidence of alarm or of serious consequences verified by pathologists, in connection with the use of the various mediums now employed. Elements of danger present in intravenous urography, which still cannot be ignored, will appear in the tables and will bear close scrutiny.

The variety of answers that our questionnaire has evoked makes one waver between the adoption of intravenous urography to the exclusion of the retrograde method and a wholesale condemnation of the intravenous method and regular use of retrograde urography. This great divergence in opinion shows a need for more uniformity in technic with regard to both methods, and a more consistent pooling of information on an unbiased level. We would hate to be deprived of either method in our own practice and are illustrating our need for both in the accompanying illustrations. Our own experiences in purely clinical practice also are at variance with those of much better observers. For instance in renal tuberculosis we have rarely found it possible to obtain satisfactory roentgenologic evidence

recourse to retrograde studies. Cabot,⁹ however, states that the pathologic changes found at operation or post mortem are usually very accurately promised by previous intravenous studies. Many writers have stressed the value (as have several in the questionnaire reports) of intravenous urography in the two specific pathologic conditions named.

Since the discrepancies mentioned exist in the minds of those in daily contact with urologic diagnosis, is it

not dangerous to announce to the general medical public that intravenous urography has brought back to general practitioners a large element of their practice, so that, presumably without help from either urologist or roentgenologist, they may now make a proper diagnosis on most patients with kidney disease?^{7b}

The questionnaire with which this presentation is concerned was prepared in order to obtain as accurately as possible the opinions of those most qualified to pass on the comparative values of intravenous and retrograde urography. Obviously, it was not practical to send copies to all the eminent urologists, even those in America, nor to many roentgenologists who, by reason of the volume of their work or a peculiar interest, might well be expected to have valuable data available. The tables were prepared after a most painstaking study of the questionnaires returned. Of the 350 questionnaires distributed, replies were received from 164, representing answers from between 225 and 235 individual physicians.

Table 2 is arranged to show the percentages of comparative usage of the two methods of urography, while table 3 depicts the percentage of instances in which intravenous urography affords (a) a positive diagnosis and (b) a confirmatory diagnosis.

with the intravenous method. In early lesions the information is not definite the finer changes not being brought out in the images on any of a long series of films while in an advanced process there has rarely been sufficient delineation for any interpretation.⁸ Likewise, in the instances of large hydronephrotic kidneys the images obtained by the use of various intravenous mediums have nearly always been incomplete. So, in the two types of disease mentioned one must have

⁹ Reply to questionnaire

In table 4 are listed the advantages of intravenous urography and its major indications, in table 5 its minor advantages and indications

Table 6 provides a composite opinion of the disadvantages of intravenous urography and indirectly points out the comparative increased value in those procedures which accompany retrograde urography

In table 7 are listed the definitely recognized contraindications to intravenous urography. Here again one must keep in mind that the retrograde method has certain dangers which might even be listed as contraindications

In connection with the collected data relative to low renal function, a number of men have reported using excretory (intravenous) urography in cases presenting a total nonprotein figure of 250 mg or more, without ill effects. Relative to hyperthyroid states, two cases presenting symptoms exaggerated by intravenous mediums were reported. Since the iodine in both neopax and diodrast is so rapidly eliminated in ordinary situations, this complication seems open to doubt, although so-called iodism may play a role in such cases. Reference to a presumed danger in intravenous urography, in cases of pulmonary tuberculosis, is made in table 7, since it was mentioned in a great many questionnaires. However, some men who are using intravenous urography in large tuberculosis sanatoriums have reported that there is no contraindication, per se, provided by this disease

TABLE 6—Major and Minor Disadvantages of Intravenous Urography

Major Disadvantages	
1 Insufficient diagnostic information due to	
(a) Insufficient filling of calices or pelvis	
(b) Too rapid elimination	
(c) Complete absence of shadow with normal kidney	
(d) Incomplete information about ureters bladder	
2 No cultural information	
3 Intestinal flatus may give misleading films	
4 Lack of detail in obese individuals	
5 Greater experience needed for interpretation	
Minor Disadvantages	
1 Technical difficulties (poor veins and other conditions)	
2 Used indiscriminately or by incompetent men	
3 Expensive if retrograde urograms are necessary	

TABLE 7—Contraindications to Intravenous Urography

1 Renal	2 Cardiovascular

(a) Liver insufficiency	(a) Hyperthyroidism
(b) Cirrhosis	(b) Pulmonary tuberculosis
	(c) Allergic states
	(d) Hyperpyrexia

Table 8 lists the fatal complications to intravenous urography. It is difficult to link up the use of any of the standard mediums used with some of the fatalities mentioned, particularly in view of the time elapsing after the x-ray studies were made.

The common reactions to the newer preparations in use for intravenous urography are shown in table 9.

A few more or less technical points which we had hoped would be discussed by those who so obligingly replied to the questionnaires, but which appeared to elicit little interest, include the adaptation of pyeloscopy

to urography in general. When mentioned in connection with intravenous urography, it was stated that the images obtained were insufficiently clear and dense to allow good visualization for fluoroscopic study. This is the tact as regards work with the fluoroscopic screen which is attached to our Cixen camera, and one of our requirements for advanced studies in motor physiology is a medium which will provide this as yet unaccomplished detail. Another point is that of lateral exposures—it is our belief that much of value can be

obtained by including one or more films exposed in a lateral or semioblique position in routine studies on the upper urinary tract. This was stressed recently by Mertz.¹⁰ One observer (H W Howard⁹) states that a lateral film taken with the suspected kidney the more distant from the film provides excellent data on kidney rotation and ptosis.

In order to provide ample illustrations of the comparative values of intravenous urography and retrograde urography, and particularly in order to illustrate the real need for both methods, the accompanying reproductions of roentgenograms are offered for inspection. In the first instance, a working diagnosis was impossible with intravenous urography, while a retrograde study readily gave a complete anatomic diagnosis. In the second instance, just the reverse was true, while in the third, both methods had to be resorted to for accurate diagnosis.

CONCLUSIONS

1 Many of the inaccuracies of both intravenous and retrograde urography are well known, and the correct balance is purely an individual problem, one must take advantage of both methods and use serial or multiple exposures at carefully chosen intervals to obtain maximum information.

2 One must be constantly reminded of the close harmony necessary between those working in the field of roentgenology and those who practice urology. Not only a mutual knowledge of an entire given clinical

¹⁰ Mertz H O and Hamer H G The Lateral Pyelogram J Urol 31 23 (Jan) 1934

picture but also joint study of diagnostic indications, especially those afforded by urographic investigations, are important to both groups for the ultimate in diagnosis

3 Our opinion is that intravenous urography has a definite role in the investigation of the urinary tract, although it is quite probable that the ideal medium and technic are still to be worked out

1144 David Whitney Building

ABSTRACT OF DISCUSSION

DR MOSES SWICK New York Like other methods in medicine, excretion urography is not without its limitations. Even cystoscopy and retrograde pyelography, despite their years of existence still have their defects. Excretion urography cannot supplant cystoscopy, retrograde pyelography and ureteral catheterization. However, one should concede that excretion urography has simplified urologic diagnosis and has eliminated to a certain extent retrograde pyelography, particularly when viewed in conjunction with the history and the physical and laboratory observations. It is simpler and less taxing to subject a patient to an intravenous urographic examination first. When corroborative or supplementary evidence is indicated or when the results are equivocal, cystoscopy or retrograde pyelography can be carried out. Excretion urography has been of considerable help in the presence of obstructive lesions of congenital origin or of lesions either obstructive or infectious superimposed on congenitally anomalous conditions under which circumstances retrograde pyelography may be mechanically impossible or dangerous. As a result congenital anomalies are being recognized clinically with greater frequency. Children, in whom pyuria has usually been attributed to pyelitis, have been found to be suffering from infections superimposed on congenital lesions, particularly the infected congenital hydronephroses. Concerning the latter it is important to bear in mind that despite comparatively little intact renal tissue good visualization may often be encountered and that therefore intense roentgenologic shadows are no quantitative criterion nor one for determining the type of therapeutic procedure. The latter will depend on the functional-anatomic status of the individual case and on the operative observations. Again in nonfunctioning hydronephrosis the mere nonvisualization of a conducting system incidental to the functional-anatomic derangement of the kidney parenchyma is in itself of great assistance as a means of localization and of diagnosis when considered together with the other clinical data. Excretion urography is well adapted to cases presenting obscure abdominal symptoms and conditions in which one is adverse or hesitates to subject a patient to the retrograde route of investigation. For example the differentiation of abdominal masses whether of intra-urinary or extra-urinary origin, has been frequently facilitated by this method of approach. In this fashion the diagnosis of congenital solitary kidney, ectopic fused kidney and dystopia of the kidney have been most important to the internist, surgeon and urologist. Excretion urography and retrograde pyelography should supplement rather than vie with each other as to superiority.

DR ROBERT E CUMMING Detroit Roentgenograms that depict both sides of a comparative study and represent investigations made on three consecutive patients seen during recent weeks supply a fair means of indicating the necessity of using both methods of urography in urologic diagnosis. I think it is dangerous for Dr Swick or any of us to select slides that may show wonderful results with one or the other of the two methods without establishing the value of the two. I believe that in most of Dr Swick's cases a diagnosis might have been made readily and safely by means of retrograde pyelography. In the three cases mentioned both methods of making urograms were necessary to complete a diagnosis in one instance and each method failed once and was successful once. When a questionnaire is returned by an excellent roentgenologist with the statement 'I have never been able to make a diagnosis with the intravenous urographic method and another sent back by a prominent urologist includes the statement 'I have seen a

number of normal kidneys removed with a diagnosis of tumor made from intravenous urographic study and when numerous other correspondents advance opposing ideas on various phases of urography and the two methods under consideration the timeliness of the discussion is most apparent

HYSTEROGRAPHY AS AN AID IN THE DIAGNOSIS OF ABDOMINAL PREGNANCY

REPORT OF A CASE

J P GREENHILL, M D
CHICAGO

There appear to be in the literature reports of only seven cases in which the injection of iodized oil into the uterine cavity was employed for the purpose of verifying a diagnosis of abdominal pregnancy. The first one to use hystero-graphy for this purpose was Bermann¹ in 1925. The others who employed this procedure were Gabaston and Harguindeguy,² Mendenhall,³ Couvleaire, Portes and Dignonnet,⁴ Osborn⁵ and Nolle.⁶ It is true that such gestations are not often encountered and even when present are frequently not suspected. However, when a diagnosis of abdominal pregnancy seems to be the correct one, injection of iodized oil into the uterus is not only a simple and relatively harmless procedure but presents absolute evidence of the presence of a pregnancy outside the uterine cavity. A roentgenogram taken of an abdominal pregnancy without previous injection of an opaque substance into the uterus frequently shows a dead or a live fetus in an abnormal location but it does not prove that the fetus is outside the uterus. A comparison of figure 1 and figure 2 will demonstrate this point.

When a roentgenogram shows a fetus that has a collapsed skull and/or other evidences of fetal death and there is a suspicion of extra-uterine pregnancy, there is surely no harm in injecting iodized oil into the uterine cavity to decide whether or not the fetus is inside or outside the uterus. Likewise in cases in which a fetus is dead and repeated attempts to induce labor by medicinal and mechanical means, such as the introduction of gauze, and bougies fail to bring about expulsion of the child, it is advisable to perform hystero-graphy. Occasionally one may be surprised to find an abdominal gestation. However, if the child is alive, together with doubt in the diagnosis it might be dangerous to inject solutions into the uterus.

REPORT OF CASE

Mrs J D was referred to me by Dr J B De Lee with a diagnosis of mature dead fetus outside the uterine cavity. He recommended that a study of the case be made by means of iodized oil. The patient was 31 years old and had a living child 3 years of age. Her last menstrual period had begun on May 13, 1934. On July 14 she experienced the sudden onset of severe cramplike pains in the lower part of the abdomen while attending a funeral. In spite of the pain she walked one and a half blocks to her home. The pain persisted and a physician was called who administered a hypodermic to relieve the pain. There was no vaginal bleeding at this time.

- 1 Bermann quoted by Gabaston and Harguindeguy.²
- 2 Gabaston J A and Harguindeguy E. *Semana med* 35 177 (May 17) 1928.
- 3 Mendenhall A M. *J Indiana M A* 22 349 (Sept.) 1929.

- 6 Nolle H. *Zentralbl f Gynak* 57 683 (March 25) 1933.

However, a few days later there was a slight bloody vaginal discharge and following this there was mild bleeding for a few days every month. During August and September 1934 the patient had severe backache and she vomited considerably. During November and December she had severe pain in the right hip. In December she had albuminuria, hypertension and edema of the hands and feet and in December and January she complained bitterly of "gas pains." She observed that the baby was considerably more active than the one in the previous pregnancy had been.

Labor pains set in on Jan. 14, 1935, and the baby ceased its activity at this time. The patient remained in bed for three days. She was given a number of hypodermics but the baby was not born. The physician in charge could not hear the baby's heart tones after January 14. Nothing was done following the three days of "labor pains." On February 22 the patient had vaginal bleeding which was associated with the expulsion of large clots. There was, however, no pain at this time. In March the abdomen was appreciably harder and smaller. On March 26 the patient bled for three days just as though she were not pregnant. On April 9 a roentgenogram showed a dead fetus, hence the physician gave the patient castor oil and quinine in an effort to induce labor. On the three successive days gauze was inserted into the uterus and pituitary substance was given for the same purpose. These measures proved ineffective. The patient menstruated normally in May and in June.

I saw the patient June 22 at which time she was in excellent health. Her general physical examination was negative and the laboratory examination gave normal results. Abdominal examination revealed a large, hard, smooth, somewhat nodular

Fig. 1—Appearance without preliminary injection of iodized oil. The fetus lies on one side of the abdomen. The collapsed skull is in the pelvic cavity near the midline. This roentgenogram does not definitely exclude an intra uterine gestation.

mass which extended up above the umbilicus in the midline but was much higher up on the left side and in the left flank. No fetal parts could be outlined and no fetal heart sounds could be heard. Vaginal examination revealed a marital outlet and a smooth hard closed cervix. In the anterior culdesac was a mass which was soft and irregular in outline and extended up toward the left side. It appeared to be attached to a small hard smooth mass which lay posteriorly and to the

right of it. The latter mass we believed to be the uterus. The irregular mass in front of and to the left of the uterus was considered to be part of the fetal sac containing the dead baby.

An Aschheim-Zondek test proved to be negative. Stereoscopic roentgenograms showed a dead fetus on the left side of the abdomen (fig. 1). On June 24 I injected iodized oil into the uterus and obtained the plate shown in figure 2. As may readily be seen, the uterus is of normal size and both fallopian tubes

Fig. 2—After the injection of iodized oil. The uterine cavity and both fallopian tubes are readily seen. The fetus occupies exactly the same position as in figure 1 but this picture shows definitely that the fetus is outside the uterus.

are elongated. The right tube passes backward and then curves forward over a rounded soft tissue shadow, which rises to the level of the fourth lumbar vertebra. (At operation this soft tissue was found to be the placenta.) The left tube passes behind the compressed fetal head and oil has collected in large drops apparently in a fluid-containing cavity in the end of the tube. The dead fetus is easy to outline on the left side. The collapsed skull is low down in the pelvis on the left side. There is no doubt whatever that the fetus is outside the uterine cavity.

It was decided to operate but before doing so, two donors were secured for blood transfusion, should this be necessary. Much trouble was not anticipated, however, because the baby had been dead for five and a half months and it was assumed that the blood vessels in the placental attachment were completely thrombosed. On June 26 thirteen and a half months after the last menstrual period I operated on the patient. On opening the abdominal cavity I found the omentum completely covering a large, round necrotic looking mass. The omentum was freed from the mass. Palpation revealed that the mass not only filled the entire lower part of the abdomen but extended about 10 cm above the umbilicus and well up into the left flank. The left part of the mass contained most of the fetus. The part low down in the midline contained the placenta and the collapsed fetal skull. There were no adhesions between the mass and any abdominal organs except the omentum. The lower pole of the mass was slightly adherent to the uterus which lay deep in the pelvis behind the fetal sac and over to the right side. The fetus, which was partly macerated was easily delivered from its sac. The child was a female and presented deformities of the arms and legs resulting from pressure

effects Examination of the patient's pelvic organs revealed that the left ovary was normal but that the left tube was congested, elongated, markedly dilated and firmly adherent to the pelvic wall on the left side The right tube was also enormously elongated and coursed over the entire anterior surface of the fetal sac While the right tube was in contiguity with the sac, it was separated from the latter by the thick wall of the sac The fetal sac lay entirely on the left side The placenta was found at the lower pole of the sac and this was slightly adherent to the uterus The right ovary could not be found anywhere Both broad ligaments were entirely normal The fetal sac and placenta were easily separated from the uterus, which was normal in every respect The right fallopian tube was removed with the mass as was also a portion of the right broad ligament, to see whether there was any ovarian tissue present in it The uterus and left tube and ovary were left in situ The abdomen was closed as usual Because of the absence of any technical difficulties the blood lost during the operation was insignificant The patient made an uneventful recovery and went home twelve days after the operation She returned

Fig 3—Deformed macerated fetus umbilical cord placenta and fetal sac

for an examination on Aug 16, 1935 She was feeling perfectly well and bimanual examination showed a normal uterus and an apparently normal left tube and ovary The right fornix was clear A normal menstrual period had occurred on July 18

COMMENT

The fetus, sac and placenta are shown in figure 3 The only possible origins for the abdominal pregnancy in this case are as follows 1 The pregnancy may have been an intra-uterine one and early in gestation the uterus ruptured and the ovum continued to grow in the peritoneal cavity after its expulsion This is hardly likely as judged from the patient's past history, the normal uterus seen on the roentgenogram and at the time of operation, and the absence of adhesions 2 The second possibility is that the patient had a tubal pregnancy, probably near the ampulla, and the ovum was extruded into the free peritoneal cavity, where it continued its development This possibility cannot be ruled out in this case even though both tubes appeared normal except for their size and course However, the absence of firm adhesions may speak against a tubal

origin 3 The third possibility is an ovarian pregnancy The diagnosis of ovarian pregnancy is favored because of the following facts

(a) The uterus was entirely normal both on the x-ray plates and on inspection and palpation at the time of operation There were no scars on it and the only adhesions to it were of the fetal sac, which were slight

(b) Both fallopian tubes were intact for their entire length, which was even greater than normal

(c) Both broad ligaments were entirely normal

(d) A careful search at the time of operation failed to reveal the right ovary

(e) The pregnancy mass was almost entirely free of adhesions, and the few adhesions that were present were very mild In advanced tubal gestations there are usually many adhesions and the placental attachment is often an extensive one Tumors that do not have a peritoneal covering nearly always become adherent to one or more structures in the abdomen The only organs in the pelvic cavity that have no peritoneal covering and still remain free from adhesions are the ovaries Since the tumor mass in the present case was smooth all the way round and almost entirely devoid of adhesions, this may be a point in favor of an intra-ovarian pregnancy

(f) The right fallopian tube coursed over and in front of the fetal sac In nearly all cases of large ovarian tumors, especially cystic ones, the fallopian tube assumes such a course As the ovarian tumor grows the tube elongates, and this occurred in the present case

(g) Microscopic study of numerous blocks of our specimen did not yield sufficiently clear-cut pictures to make a definite diagnosis, probably because the fetus had been dead for five and a half months and the tissue had degenerated However, in one block there was a layer of cellular tissue that resembled ovarian cortex and adjoining it was definite chorionic tissues

SUMMARY

A case of abdominal pregnancy, probably ovarian in origin, is reported not because of the rarity of such gestations but to emphasize that a diagnosis of abdominal pregnancy can be made with certainty by injecting iodized oil into the uterine cavity I believe this procedure should be employed in every case in which the diagnosis of abdominal pregnancy is strongly suspected, especially if clinical signs and x-ray plates show that the baby is dead In the presence of a dead baby this procedure is practically harmless

55 East Washington Street

Progress and the Experimental Method—In all ages the implicit belief in orthodox theory or in authority has been the greatest bar to scientific progress What chance was there of learning anything about the etiology of disease when every one believed for nearly a thousand years that disease was caused by some chance alteration in the admixture of four humors that no one had ever seen or demonstrated experimentally Galen was a very great man, but medicine would not have gone backward for a thousand years had it not been for the slavish worship of his authority Galen himself was an experimentalist His followers swallowed his books whole and until the time of Vesalius considered it heretical to even question his anatomy in spite of the fact that Galen never dissected a human body Progress in scientific medicine has depended almost exclusively upon the experimental method Hypotheses or theories are only useful when they lead to experiments to test their validity They are an impediment when they are accepted without such experimental validation and become orthodox beliefs—Vedder, E B The Development of Tropical Medicine *Am J Trop Med* 16 1 (Jan) 1936

A FUNDAMENTAL, RECIPROCAL RELATIONSHIP BETWEEN MYELOID AND LYMPHOID TISSUES

ITS RECOGNITION, NATURE AND IMPORTANCE AS REVEALED BY EXPERIMENTAL AND CLINICAL STUDIES

B K WISEMAN, MD

C A DOAN, MD

AND

L A ERF, MD

COLUMBUS, OHIO

Progress in the solution of the problems of disease in man must depend to a considerable degree on fundamental progress in the recognition and interpretation of alterations in disturbed physiologic equilibria. It may be true that physiology "has its own problems, great in number and enormous in complexity, and those of disease are not among them".¹ Nevertheless, experience has established that the origin and explanation of many abnormal states may be traced to deranged physiologic processes and more particularly to disturbed physiologic equilibria. Granted that this is beyond the scope of pure physiologic research, the recognition of states of physiologic imbalance and of pathologic alterations produced in the tissues by this imbalance then becomes an important concern of the clinical investigator. That this "borderline" territory between physiology and medicine has proved a very fruitful field for clinical investigation, in one direction at least, is quite apparent when one reviews the important progress that has been made in the diseases characterized by disturbances in the functional equilibria of the endocrine glands. It is clear that this field of physiologic disequilibria, occupying as it does a middle ground between medicine and physiology, is in real danger of neglect, although it is potentially very important in the search for and the explanation of the mechanism of disease.

It is our purpose in this paper to bring together and to organize a number of observations both experimental and clinical, which have been accumulated in recent years in our laboratory from a widely divergent series of investigations and which when taken together, constitute a body of fact pointing strongly toward the existence of a fundamental physiologic reciprocal relationship between myeloid and lymphoid tissues. The importance of this concept to certain clinical blood dyscrasias will be emphasized.

EXPERIMENTALLY INDUCED IMBALANCE OF THE CELLS IN THE CIRCULATING BLOOD

For a number of years we have been investigating the fundamental cellular reactions occurring in bone marrow and in the lymphatic tissues not only in the course of natural disease but also, more particularly, as these tissues have been brought individually under the influence of substances that have a specific stimulatory effect on them. The demonstrated effectiveness

of nucleic acid derivatives in promoting myelopoiesis,² and of native proteins in inducing lymphopoiesis³ each specific for the tissue designated has been the subject of repeated communications from this laboratory and requires no further elaboration in this paper. Experience has proved that profound and sustained disturbances in the normal numerical balance between the granulocytes and the lymphocytes of the circulating blood regularly follow the daily intravenous administration of either of these substances in rabbits.

Disturbed Equilibrium Due Primarily to Myeloid Imbalance—In our series of studies of myelopoiesis more than fifty rabbits have been injected intravenously with varying quantities of nucleic acid derivatives. Rabbit 0-81, one representative of this group, received sodium nucleinate daily over a period of four months. Starting with 50 mg the quantity was periodically increased until during the final month of the experiment 1 Gm of nucleinate in 10 cc of sterile physiologic solution of sodium chloride was given intravenously each day (fig 1). During the period of base line control counts, Dec 10 to 23 1930 it will be observed from figure 1 that the lymphocytes fluctuated between 4,000 and 5,800 per cubic millimeter of blood and that the neutrophilic granulocytes ranged between 900 and 2,000 per cubic millimeter of blood. Beginning with the sodium nucleinate injections, however, the granulocytes rose promptly and steadily during the first month, Dec 23, 1930 to Jan 21 1931, but in addition there was a precipitous reciprocal fall in the lymphocytes. From January 21 to March 17 the neutrophilic leukocytes equilibrated on a plateau at an average of 6,000 cells per cubic millimeter of blood, during which time there were marked fluctuations in the total lymphocytes, the latter breaking through from the low point of 600 cells per cubic millimeter to temporarily higher levels, particularly on February 5 and 19. Although the granulocytes were pushed to still higher levels during the last month under the influence of daily 1 Gm doses of sodium nucleinate the lymphocytes stabilized at an average value of 3,000 cells per cubic millimeter, or at about 70 per cent of the preinjection level.

An autopsy was performed on this animal April 15, after termination of the experiment, by lethal injection of air.

The microscopic examination of these two tissue systems confirmed the gross appearances. The bone marrows were found without exception to be definitely hyperplastic the hyperplasia being confined entirely to the neutrophilic or amphophilic myelocytes. The erythropoietic foci were both relatively and absolutely decreased in size and number. The myeloid hyperplasia was particularly apparent in the spleen and in the kidney,^{3a} the latter organ being an exceedingly rare site for hematopoietic foci. In striking contrast to these tissues, the lymph nodes showed a degree of atrophy never before witnessed in the rabbit. Large acellular spaces filled with tissue fluid were abundant and replaced areas normally very cellular. Cells of the lymphoblastic series were infrequent, those cells remaining being old or degenerating lymphocytes. Some increase in fibroblasts was evident, although no actual scar tissue was found (fig 2).

Artificially induced neutrophilic leukocytosis and myeloid (neutrophilic) hyperplasia under the conditions

of this experiment are accompanied consistently by a reciprocal lymphopenia and marked lymphoid hypoplasia

Disturbed Equilibrium Due Primarily to Lymphoid Imbalance—Experiments paralleling those just given except that stimulus to the lymphoid structures was induced by the intravenous injection of foreign protein

Fig 1—Blood changes in rabbit 081. This animal received intravenous injections of sodium nucleinate daily in increasing dosage as shown. Note the rise in granulocytes that occurred with the depression in lymphocytes and red blood cells

were carried out in a series of rabbits totaling twenty-three. Foreign proteins from various sources were found capable of invoking the response herein detailed but because of ease of preparation and adequacy of supply of fresh material, egg albumin was used as the principal stimulating agent. Typical of the reaction in this group may be cited the blood examinations from animal 0-318 (fig 3). The period prior to March 21 consists of three and one-half months of base line control counts. Beginning March 21, 1934, and daily thereafter this animal received 50 mg of egg albumin in 5 cc of physiologic solution of sodium chloride given intravenously. A study of figure 3 shows that seven days after the first administration of this substance the peripheral level of lymphocytes began to rise and remained constantly elevated throughout the entire course of the experiment. A further study of this chart reveals the fact that the rise in the lymphocytes was accompanied by a sharp reciprocal fall in the neutrophilic granulocytes the latter reaching a low point of only 480 cells per cubic millimeter of blood, April 7, coincident with the period during which the lymphocytes reached their high peak. Following this episode it will be observed that as the foreign protein became less effective in calling forth lymphocytes, probably because of the increasing precipitin titer of the serum against egg white, there was a corresponding partial recovery in the granulocytic levels (April 7 to

16) followed by a definite upturn in the numerical values for this cell type beginning April 20, the granulocytes and lymphocytes attaining a common proportionate representation in the blood ten days later

Gross examination of the myeloid and lymphatic tissues of this animal as seen at autopsy revealed wide spread changes, which were typical of all the animals in this series. Extreme hypoplasia of the bone marrow was evident in all the long bones, the regressive changes being evidenced by fatty replacement of a large part of the marrow cavities normally rich in myeloid cells. All deposits of lymphatic tissue were grossly enlarged, the popliteal node exceeding the average normal for this animal more than five times by weight. The spleen weighed 24 Gm, as contrasted with the average normal of 0.7 Gm. On cut section the nodes were very cellular, and supravital examination of the scrapings showed a considerable increase over the normal in lymphoblastic cells. The malpighian bodies were prominent and numerous, some of them measuring almost a millimeter in diameter.

Microscopic examination of the bone marrow confirmed the gross appearance. Figure 4 represents a low power view through a typical atrophic area. It will be observed that in these fields there is almost total aplasia. Other areas from the long bones, not visibly altered in the gross, nevertheless showed definitely less blood cell formation than normal. The diminution or absence of megacaryocytes was particularly striking. Microscopic study of the marrow from ribs and sternum failed to show definite changes of any kind. This was not wholly unexpected, as it is the usual experience to find the marrow in these locations the last to be affected and the first to respond in hypoplastic

Fig 2—Section through the cortex of a popliteal lymph node from rabbit 081. This animal had received intravenous injections daily for approximately two months of sodium nucleinate in increasing dosage of from 0.05 to 1 Gm. Note the absence of cells in this area which normally is very cellular. The absence of young lymphocytes is also a feature. Oil immersion view.

states and recovery was already occurring in this animal at the time of the autopsy.

Microscopic changes of the lymphatic tissues in contrast to the bone marrow showed undoubted hyperplasia. In many of these nodes proliferating lymphoid tissue almost completely filled the medulla of the node.

thus converting this structure into a mass of diffuse lymphatic tissue with obliteration of the normal cortico-medullary architecture. The spleen was especially rich in lymphocytes, neighboring follicles often becoming confluent (plates 1 and 2 in former publication⁵).

The data assembled from this group of animals indicate that experimental stimulation of lymphatic ele-

dissection of the blood picture. Nevertheless striking examples of the effects which may become manifest in human disease when this physiologic balance between myeloid and lymphoid tissues is impaired have been observed. As may be anticipated, these tissue and blood responses are most clearly defined when the stimulus is somewhat specific for, and limited to, one or the other of the blood-forming tissues.

Infectious Mononucleosis—Infectious mononucleosis affords an excellent example of a disease in which lymphoid hyperplasia is commonly almost the sole pathologic feature present. A study of the blood cells in some thirty-two cases which we have observed shows quite regularly that the high values for the lymphocytes are accompanied by low relative and absolute values for the granulocytes. Figure 5 shows this phenomenon graphically. This patient was first seen about eighteen hours after the clinical onset of symptoms. There was the usual malaise, Vincent's infection of the tonsils, generalized adenopathy and a barely palpable spleen. Following our first observation, Sept 8, 1933 the lymphocytes, already distinctly elevated and showing the characteristic qualitative changes, rose steadily to a maximum of 8,800 cells per cubic millimeter of blood by the 11th. Accompanying this rise in lymphocytes there was a steady decrease in the circulating granulocytes, these cells reaching the very low value of 500 neutrophils per cubic millimeter of blood September 15. Concurrent with the subsequent fall in lymphocytes it will be observed from this chart that the granulocytes rose sharply, reaching the normal value of 4,000 cells at the same time, October 11, that the lymphocytes returned to within their normal level of 3,000 cells per cubic millimeter of blood. Following this there was a further slight rise in the lymphocytes, which was accompanied by a slight drop in the granular cells (October 11 to December 13), and finally a sharp drop

Fig 3—Blood changes in rabbit 0318. This animal received intra venous injections of 50 mg of egg albumin daily for forty one days. Note the depression in granulocytes which occurred simultaneously with the elevation of lymphocytes. The developing anemia is clearly shown. The animal gained weight constantly throughout this experiment.

ments with foreign protein results in a reciprocal reduction in the myeloid elements. It is again apparent that the overgrowth of one type of blood-forming tissue influences adversely the growth of the other. The fact that the monocytes are unaffected during these changes in the myeloid and lymphoid elements attests further to the limited two-way specificity of this reciprocal reaction. It is well known that the monocyte depends neither on the bone marrow nor on the lymphatic tissues for its origin arising in the diffuse connective tissues distributed everywhere in the body.

It would appear, therefore that there is a constant physiologic balance or reciprocal relationship existing between the myeloid and lymphatic tissues which controls and in turn is reflected by a constantly changing ratio of granulocytes to lymphocytes in the peripheral blood in response to normal and pathologic stimuli. The importance of this fundamental law of reciprocal hemtopoiesis is at once apparent in the interpretation of the blood pictures produced by disease.

CLINICAL STUDIES OF MYELOID AND LYMPHATIC IMBALANCE

Many factors each having a specific and often divergent influence on the blood cells are always present in clinical disease. Fever alone exerts a powerful influence on the blood-forming tissues and has only recently been scientifically appraised⁶. Many other influences not yet studied undoubtedly serve to alter the blood response in disease, so that the demonstration of relatively 'pure' clear-cut reactions such as may be obtained in the experimental laboratory is as a rule not possible in the clinical patient. That is to say the reactors in disease are multiple and often result in cellular responses that tend to becloud an interpretative

Fig 4—Section through the bone marrow of the femur from rabbit 0318. This animal had received intravenous injections of egg albumin 50 mg daily for forty one days. Absence of myeloid activity and fatty character of this marrow is clearly shown. Low power view.

in the lymphocytes coinciding with an equally sharp rise in the granulocytes. It will be observed that during this entire period there was a slight fall in the red blood cells most marked when the lymphocytes were highest and leveling off when these cells were near the limits of normal. At the last observation the lymph node, in this individual were still quite definitely enlarged and

⁵ Wiseman B. K. J. Exper. Med. 54: 271 (Aug.) 1931.
⁶ Hargraves M. M. and Doan C. A. Proc. Fifth Annual Fever Conference Dayton, Ohio, 1935, p. 51.

it will be observed that neither the red cells nor the granular cells had returned quite to normal. This would seem to be best explained, in view of the experimental work cited, by attributing the obvious depression of the bone marrow to the inhibitory effects of the lymphatic tissue.

Hypoplastic Anemia—This is usually regarded not as a clinical entity but as a state of hemocytologic deficiency directly traceable to the effects of a variety of etiologic agents. Certain toxic substances, notably benzene,⁹ x-rays and radium,¹⁰ arsphenamine,¹¹ trimethyltoluene,¹² and bacterial toxins¹³ depress marrow function. In multiple myeloma and in widespread tumor metastases to the marrow,¹⁴ active hematopoietic tissue is destroyed by mechanical displacement. After due recognition is given to all the known causes which tend to depress the formation of the elements that take their origin in the bone marrow, however, there remains a residual so-called idiopathic group in which the etiologic factor or factors is not so obvious. Some of these cases appear to be identified with states of

Fig 5—Blood changes in patient V L showing the reciprocal relationship between lymphoid and myeloid cells

unexplained lymphoid hyperplasia that are not clearly either lymphosarcoma or leukemia. The following case suggests that altered relative volumes of lymphatic and myeloid tissue may be important in determining or initiating progressive hypoplasia of the bone marrow in some cases in this "idiopathic" group.

CASE 1—A white girl aged 3 years admitted to the University Hospital, Aug 22, 1934 complained chiefly of pallor and weakness, which were said to have been present for two weeks prior to admission. The past history revealed no significant facts. On examination, the patient appeared to be

acutely ill, she was very pale, the respirations were rapid but there was no evidence of loss of weight, the tonsils were large, the pharynx was injected, the cervical glands were large, discrete, not attached to the skin and not tender. The epitrochlear, axillary and inguinal glands also were enlarged, ranging in size up to that of a lima bean. When the abdomen was examined the liver was found to be enlarged to 7.5 cm below the costal margin in the right anterior axillary line. The spleen extended down 2 cm below the left costal margin. Blood count performed on admission showed 3,200 white blood cells, 1,065,000 red blood cells, platelets 11,000 per cubic millimeter and hemoglobin 39 Gm per hundred cubic centimeters of blood, reticulocytes 0.1 per cent and a differential of 16 per cent polymorphonuclears, 2 per cent metamyelocytes, 2 per cent myelocytes, 78 per cent lymphocytes and 2 per cent monocytes. There was a shift to the left in the lymphocytes, but no leukemic cells were found. The clinical diagnosis was aplastic anemia with terminal secondary infection. Autopsy was performed by Dr H L Rhinehart, pathologist to the University Hospital. There was moderate hypertrophy of the lymphoid tissue, especially the retroperitoneal, mesenteric and perigastric nodes with prominent Peyer's patches and solitary follicles. Peripheral nodes were increased in size and seemed to be slightly fibrous on cut section. Bone marrow removed from the right femur tibia sternum and ribs showed the marrow cavity of normal size, filled with soft marrow, apparently fatty on the periphery and hemorrhagic in the center. Supravital scrapings from these areas showed very few cells.

Microscopically the lymph nodes (fig 7) showed many young lymphocytes and diffuse hyperplasia with invasion of the medulla by hyperplastic lymphoid tissue. There was definite increase in lymphoid tissue about the gastro-intestinal tract. The liver showed marked atrophy and degeneration about the central veins and lobules cloudy swelling throughout, and milary abscesses. The spleen showed marked increase in pulp with considerable congestion and very active malpighian bodies. The bone marrow sections (fig 8) throughout showed marked atrophy with considerable fibrous tissue proliferation. The remainder of the microscopic examination did not reveal anything additional to that observed in the gross. There was no evidence of leukemic infiltration in any of the tissues.

Both the clinical and the microscopic changes seemed to be quite classic for aplastic anemia, with terminal secondary infection, except that there was moderate to marked lymphoid hyperplasia. It is difficult to harmonize the adenopathy with the bone marrow hypoplasia on the ground of terminal infection alone, as it is well known that infectious states tend to cause atrophy rather than hypertrophy of the lymphoid tissue. It is significant that the lymphoid tissues were found to be unusually active in contrast to a relatively inactive bone marrow. It would seem, in view of the reciprocal reactions cited, that one must consider the possibility of a specific depressive effect on the bone marrow through an overbalance of the lymphatic components.

The observation of a second case similar to that described establishes the fact that, at least in some cases of "aplastic" anemia, the reduced volume of active myelopoietic tissue occurs in association with a reciprocal increase in the volume of lymphoid tissue.

Recent work has emphasized the effects produced on the bone marrow by surgical removal of the spleen.¹ In many instances, extirpation of this organ is followed by increased hematopoiesis with elevated levels of cells in the peripheral blood. After due consideration is given to local factors of sequestration and destruction of blood cells there still remains an apparent effect of the spleen on the bone marrow which tends to regulate

downward the production of these cells. In explanation of this relationship it has been suggested that there may be a direct inhibitory effect of the spleen on the bone marrow similar in nature to that of a hormone influence. Since the spleen represents the largest single accumulation of lymphatic tissue in the body, the experimental data in this communication give weight to the interpretation of the postsplenectomy-cellular increases from the marrow on the basis of the elimination of a substantial volume of lymphatic tissue. This establishes a rationale and provides the explanation for the favorable effects observed by therapeutic removal of the spleen in selected cases of "aplastic" anemia.

The important point to be determined is whether the hypoplasia of the bone marrow is primary or secondary to an overgrowth of the lymphatic structures. It is believed that the evidence for reciprocal hypoplasia and hyperplasia as furnished by the cases of leukemia which follow provides in addition to the experimental evidence substantial reasons for favoring the latter explanation over the former.

THE LEUKEMIAS

A Lymphatic—It has been held generally that the widely observed depression in bone marrow function which usually accompanies lymphatic leukemia is a result of the mechanical crowding out of the myeloid and erythroid elements by the infiltration of lymphatic elements. The relative importance of this mechanism in determining "symptomatic" hypoplasia of the marrow tissue, however, has not been established. In no other tissue of the body does lymphoid infiltration produce such widespread, almost total, failure of function and destruction of a parenchymatous organ. On the other hand, if the chief force that determines hypoplasia of the marrow elements in lymphatic leukemia is the increased volume of lymphocytes elsewhere acting through a specific reciprocal inhibitory influence rather than by mechanical pressure, hypoplasia of the bone marrow should be found in cases in which there is minimal evidence of the infiltration phenomenon. The following case of "aleukemic" lymphatic leukemia provides evidence that increased volume of lymphatic tissue and not marrow infiltration may be an important or even the chief determining factor in the hypoplasia of the bone marrow in lymphatic leukemia.

CASE 2—A child aged 2 years, admitted to the University Hospital, Feb. 10, 1935, complained of weakness, pallor and purpuric phenomena.

During the stay in the hospital of forty-nine days the anemia and tendency to hemorrhage was combated with four blood transfusions, but the case ran the usual course of a leukemia with several relapses followed by partial remissions. The patient died showing widespread hemorrhages from the mucous membranes and into the skin. The blood examination at the time of death showed 12,000 white blood cells, with a differential of polymorphonuclear leukocytes 10 per cent, myelocytes C 4 per cent, lymphocytes 82 per cent and monocytes 4 per cent. The red blood cells were 2,200,000, platelets 29,000 and hemoglobin 5.8 Gm per hundred cubic centimeters of blood. The autopsy was performed by Dr. Reid Joyce and in abstract revealed the following: There were purpuric spots on the scalp and over the cheeks, abdomen, chest, back and lower extremities. The occipital, cervical, axillary and inguinal nodes were distinctly enlarged and varied in size from a pea to that of a lima bean. The lymph nodes of the mesentery, the lumbar chain and the tracheobronchial trunks were particularly prominent, individual nodes reaching the size of a walnut. The liver weighed 650 Gm and extended 5 cm below the costal border in the right mammary line and 6.5 cm below the xiphoid process of the sternum. The spleen weighed 200 Gm and extended below the costal border 2.5 cm. With the exception

of hemorrhage into the parenchyma, the kidneys were not abnormal grossly. There were numerous hemorrhagic areas on the surface of the peritoneum, pleura, epicardium and endocardium. No pneumonia or tuberculosis was evident in the lungs. Bone marrow was secured from the tibia, femur, ribs and sternum and appeared in the gross to be marked by widespread hemorrhage and an increase in fibrous tissue.

The microscopic sections, with the exception of the bone marrow, revealed the usual lymphoid changes that are characteristic of lymphatic leukemia. The bone marrow was definitely hypoplastic without significant lymphoid infiltration in the areas studied. Only an occasional area showed the presence of many infiltrating leukemic cells. Figure 9 shows a section through the sternum, usually hyperplastic, in illustration of the presence of hypoplasia of marrow elements without concomitant lymphoid infiltration.

B Myelogenous Leukemia—Generalized swelling of the lymphoid structures in cases of myeloid leukemia is an almost constant feature of this disease. The reaction occurring within these structures which gives rise to such enlargement is, however, not clear beyond the fact that the cellular content is predominantly myelocytic. Protagonomists of the unitarian theory of blood formation hold that the myeloid cells arise in situ by virtue of the metamorphosis of the (totipotent) lymphoid elements. In contrast to this is the belief of many adherents of the polyphyletic doctrine that the explanation for the enlargement of the lymphatic nodes lies in the fact that these structures are infiltrated with primitive myeloid cells, in common with the other tissues throughout the body, and that these cells proliferate in exactly the same fashion as occurs in the bone marrow, the intrinsic lymphoid elements remaining passive and not undergoing myeloid metaplasia.

The following case of myeloid leukemia provided an opportunity not only to observe the histologic effects on lymphoid tissue when myeloid stimulation was dominant but also to clarify considerably the controversial points discussed in the foregoing paragraph.

CASE 3—A white boy, aged 11 years, was admitted to the pediatric service in the University Hospital, Jan. 29, 1934, and a diagnosis of acute myeloblastic leukemia was made.

Autopsy was performed August 6 by Drs. Lacey and Hargraves. The gross examination, in abstract, revealed an extensive sloughing lesion of the left side of the face with loss of the entire cheek and the left half of the mandible. There was an almost complete absence of subcutaneous fat. The peripheral lymph nodes were not palpable. The liver extended 5 cm below the costal border and weighed 970 Gm. The spleen extended to the costal border, weighed 250 Gm and showed multiple white areas about 1 mm in diameter. The lymph nodes, both superficial and deep, were very small, measuring from 2 to 5 cm in diameter, and were difficult to find. There were about 200 cc of clear straw colored pericardial fluid and about 500 cc of blood-tinged fluid in the peritoneal cavity. The bone marrow of the entire skeleton was characterized by extreme hyperplasia of gray tissue.

Microscopic study showed extreme myeloid hyperplasia of all bone marrow tissues, with a predominance of early myeloid cells. The spleen was heavily infiltrated with myeloid cells, and the lymphocytes of the malpighian bodies were largely replaced with myelocytes and myeloblasts. The lymph nodes presented a remarkable picture. On section they cut with greatly increased resistance, scrapings for supravital examination were obtained with great difficulty, and only a few cells could be found. All nodes showed a marked degree of atrophy, and the lymphocytes obtained from them were nearly all old types. Only an occasional myelocyte was found, but fibroblastic proliferation was prominent. Figure 10 shows the degree of atrophy and the absence of myeloid infiltration that characterized all the nodes.

This case afforded an opportunity to observe the state of the lymphoid structures when infiltration with myeloid elements was not present. Under such circum-

stances, the degree of atrophy of the lymphoid structures was remarkable. Fibrous tissue replacement of the normally rich lymphocytic areas in the nodes was comparable to that observed in the nodes of the animals with nucleinate induced leukocytoses. It was also noteworthy that although the bone marrow was hyperplastic for myeloid cells very few of these cells were found in the lymph nodes. The latter fact suggests that myelopoiesis, when it occurs in the lymph nodes, arises from metastatic cells and not from stimulation of the primitive cells preexisting in the nodes, since it is clear that in this case the stimulus for myeloid proliferation, although still dominant and effective in the body as reflected in the bone marrow, failed to stimulate the primitive cells in the lymphoid tissue to myeloid proliferation. In fact, quite the opposite condition prevailed, since atrophy and diminution in all cellular elements was the net result. It is felt that the tissue reactions in this case provide strong evidence for the theory of a reciprocal relationship existing between lymphoid and myeloid tissues in that the specific stimulus for myelopoiesis was accompanied by inhibition of lymphopoiesis in lymph nodes which did not show infiltration of myeloid cells.

COMMENT

The evidence cited, both experimental and clinical, strongly suggests the existence of a definite physiologic equilibrium between myeloid and lymphatic tissues. There would also seem to be some ground for the belief that physiologic and pathologic disturbances of this balance may lead to definite blood anomalies. While the evidence is only suggestive and not conclusive that lymphoid imbalance may play an etiologic role in the production of a specific type (not all types) of "aplastic" anemia, we nevertheless feel that the interpretation of the facts observed justify further consideration, study and experiment.

There would seem to be only two possible explanations for the reciprocal phenomena observed, as shown in the accompanying tabulation. First may be suggested the existence of a single substance (molecule) having stimulatory properties in one location and inhibitory effects in another location for the common stem cell. This hypothesis would seem to be decidedly contrary to both experience and logic. Modern beliefs relating to blood formation indicate that at least with respect to the white blood cells, all stem cells, wherever found are identical in potency.¹⁶ That they differentiate along dissimilar lines is the result of different environmental influences, different stimuli, or both. This explanation of the physiology of blood formation makes it extremely difficult to conceive of a single substance that could affect the same cell so differently with only the added help of a conditioning environment.

The only other obvious explanation that could adequately explain the facts of reciprocal response is integrated with the concept of a physiologic cellular equilibrium. This hypothesis entails the corollary that any considerable increase in the volume of either tissue must result in a corresponding diminution in the volume of the other. The experimental and clinical observations available apparently confirm this theoretical explanation and no facts at present contradict it. Positive proof must await further direct experiment. The mechanism whereby this equilibrium is physiologically controlled can be only a matter for speculation at this

time. Possibly there is only a limited and fixed amount of maturative substance essential for maturation present in the body at any one time, and a diversion of this material to one or the other of the actively growing tissues results in a deficit in supply to the other, the latter therefore undergoing involution. Possibly there is a specific inhibitory influence of each tissue on the other. Whatever the method whereby the equilibrium is controlled, it seems quite certain that some of the factors that influence or effect the balance of these tissues are clear. Endogenous or exogenous stimuli, toxins and similar substances specific for each cell type are undoubtedly important in disturbing the physiologic equilibrium. It is also certain that mechanical and physical factors may definitely alter the normal balance of these cells. This discussion therefore makes it probable that, fundamentally, two distinct types of clinical disease are theoretically possible as a result of a disturbance in this normal relationship: one in which the disturbing factor is secondary to an abnormal state elsewhere (example, infectious mononucleosis), and second, a type in which the disturbance is intrinsic and due to a failure of physiologic control (cited cases of "aplastic" anemia). Irrespective of the merits of the speculations herein, it is certain that the phenomena of reciprocal relationships of the blood cells must be considered henceforth in the interpretation (1) of the mechanism of cellular reactions, (2) of the microscopic changes in the blood forming tissues and (3) of the peripheral blood elements, not only in disease states in general but more especially in the blood dyscrasias.

SUMMARY

1. Experimental induction separately of myeloid and lymphoid tissue hyperplasia in rabbits suggests that hyperplasia of each tissue occurs at the expense of hypoplasia in the other. These changes are usually reflected in the peripheral blood by a reciprocal alteration in the levels of the myeloid and lymphatic cells.

2. Observations on the blood and tissues in certain clinical diseases provide instances in which this reaction is apparently responsible for some of the hitherto puzzling blood and tissue alterations regularly found.

3. It is suggested that disturbances of physiologic origin which alter the normal balance of blood-forming tissues may be important in the etiology of some of the blood dyscrasias. Two cases of "aplastic" anemia with unusual features, which have been cited possibly belong to this class.

1995 Tewksbury Road

ABSTRACT OF DISCUSSION

DR. E. B. KRUNBHAAR, Philadelphia. I am more impressed by the experimental evidence than by the clinical. Physicians are obviously handicapped in their approach to the study of an individual clinical case as compared with a similar study of experimental material and by the limitations of our ordinary blood counting technique. For instance, if one wants to get the absolute numbers of lymphocytes in a normal case and in a case of leukemia, one takes the total count of a normal case, say 8,000 leukocytes, and, if there are 25 per cent lymphocytes, that will give 2,000 lymphocytes. That figure is reached by taking a very small sample of blood as the basis for the total count and an equal amount of blood for the differential count. They are different samples in which a very small number of the actual cells are counted the results being applied to large figures. There are numerous possible sources of error in such a technique. On the other hand, in a myeloid leukemia count, say 800,000 cells, of which only 1 per cent are lymphocytes by the differential smear, that would give 8,000 lymphocytes. It would have to be admitted that one could easily get 15 per

¹⁶ Wiseman, B. K. The Origin of the White Blood Cells. J. A. M. A. 103: 1524 (Nov. 17) 1934.

cent instead of 1 per cent, which would give 12,000 lymphocytes instead of 8,000. It is easy to see that the possible error in such a method is very large. I don't mean in any way to imply that the authors' counts are due to such errors, but such difficulties should be taken into account when one is studying clinical material and making deductions from these methods. Both the lymphocytes and the granulocytic series are concerned with resistance of the body to noxa of various kinds—to be sure, with different phases of the problem, but still enough on the same side that one would expect a priori, a synergistic relation of these two types of blood cells rather than a reciprocal inhibitory effect. Also one must take into account the occurrence of multiple stimuli which may override reciprocal relationship. That offers a perfectly logical explanation of such clinical cases when one fails to find this relationship but instead finds an increase of both polymorphonuclears and lymphocytes and other elements. However, if one has to take such exceptions into account and explain them in that way, it seems to me that that robs the clinical evidence of some of its significance. None of this, however, applies to the experimental evidence, which to me was very convincing, as were the histologic pictures of the marked inhibitory changes in the appropriate tissue. The remarks that I have brought forward should be taken in the light of suggestions for future study of the problem.

DR B K WISEMAN, Columbus, Ohio. This type of work, just as in all hematologic work, is in a state of flux at this time, and it will take many years to reveal the true significance of the investigative approaches being made from many angles.

Clinical Notes, Suggestions and New Instruments

PERFORATION OF THE GALLBLADDER WITH MASSIVE INTRAPERITONEAL HEMORRHAGE

WILLARD BARTLETT JR MD AND ROBERT W
BARTLETT, MD St Louis

Perforation of the gallbladder is itself an uncommon lesion but, when accompanied by massive hemorrhage, is an event of extreme rarity. A review of standard surgical textbooks, such as those of Babcock, Da Costa, Homans and Ashhurst, and of the Nelson and Lewis systems, discloses no mention of gross hemorrhage as a complication of perforation of the gallbladder. Moreover, one finds no reference to it in the large series of cases of perforated gallbladder reported by various authors. In reviewing the literature since 1900 we found mention of only two cases similar to the one reported herewith.

Waters¹ reports the case of a 63 year old woman who was seen after four days of illness with an abdominal emergency. Abdominal exploration was made with a tentative diagnosis of intestinal obstruction. Free blood and clots were encountered everywhere in the abdomen. "When the gallbladder was palpated the exploring hand withdrew about ten faceted stones of varying size. The true condition was then recognized." Further investigation revealed a perforation at the gallbladder neck, which had torn the cystic artery, there had been no local effort at walling off the perforation. About 200 stones were removed from the gallbladder after its fundus had been opened. Then, since the patient was in a precarious condition, a hemostat was placed at the neck of the gallbladder below the site of rupture and another along its hepatic attachment. A gauze pressure pack was then placed under the neck of the gallbladder. The patient recovered after a stormy postoperative course and was discharged about a month after admission to the hospital.

Schwyder² records the case of a 72 year old man who entered the hospital in a moribund condition two days following the onset of abdominal pain and vomiting. Death occurred within a few hours, and autopsy disclosed about two liters of free blood and clots in the abdominal cavity. The gallbladder was thickened and had suffered a tear 4.5 cm in length through the

site of an ulcer 4.5 by 2 cm situated in the wall of the free portion of the gallbladder. In the fundus was a much smaller, very deep ulcer showing grossly an eroded open blood vessel. The gallbladder contained no stones. It was the implied contention of the author that the erosion of the vessel resulted in bleeding into the gallbladder, and the subsequent rupture of the weakened wall at the site of the larger ulcer. No microscopic characteristics of either ulcer were described.

REPORT OF CASE

History—The case we report is that of Mrs C P, aged 65, white, a housewife, who was admitted to the Evangelical Deaconess Hospital, Feb 11, 1935, at noon, with chief complaints of abdominal pain distention of the abdomen and constipation.

During the past year, two attacks of pain occurred in the epigastrium and between the scapulae, waking her at about 3 a m, with vomiting once in each attack followed by immediate relief of pain and return to sleep. February 9 a similar attack recurred but pain persisted, continuing thereafter being generalized with a slight tendency to localize in the lower quadrant. Abdominal distention came on within two hours and had been unreheved by countless enemas since. Vomiting occurred three times February 9, twice on the 10th and twice early on the 11th, but never a larger amount than ingested. There were two soft normal stools shortly after the onset of pain, no passage of stool or flatus had occurred since. There was slight frequency of urination with the present attack, no burning, pain or hematuria was observed.

The family history was irrelevant. The patient had never had any serious illness or operation. She had had dyspnea on exertion for years. There were no food idiosyncrasies. Stool occurred daily without physic. An uneventful menopause occurred at 52. There were several children living and well. The husband was in good health.

Physical Examination—We first examined the patient in her home in consultation with her physician, Dr Edward H Eyerman, at 3 p m, February 10. The patient was obese, obviously dehydrated and in considerable pain. The temperature was 100 the pulse 85. The abdomen was distended and the diaphragm elevated, there was generalized slight abdominal tenderness possibly more pronounced in the epigastrium. There was no peristalsis to auscultation no masses or viscera were palpable. Leukocytes numbered 15,000. A tentative diagnosis of low intestinal obstruction associated with some such intraperitoneal infection as a perforated diverticulum was made, and immediate removal to the hospital was urged. Our combined efforts toward this end were unavailing.

On examination after admission to the hospital the following day at noon, more dehydration was evident in the dry tongue sunken eyes and skin. Examination of the head and neck gave negative results. The heart and lungs were normal except for a snapping second aortic sound. The abdomen was distended and presented generalized tenderness, no rigidity, but dullness in the flanks. The patient voluntarily indicated the right lower quadrant and the right flank as the source of her trouble. Pelvic and rectal examinations were negative, the temperature 104.4, pulse rate 102, respiration 40, blood pressure 165 systolic and 70 diastolic, hemoglobin 62 per cent, erythrocytes 3,396,000 leukocytes 20,000. The Schilling count showed segmented forms 78 per cent, stabs 10 per cent, lymphocytes 11 per cent and monocytes 1 per cent. Voided urine obtained somewhat later was acid, of amber color, specific gravity 1.025, albumin negative, sugar positive (intravenous administration), bile negative, indican positive and acetone positive. Microscopically there were 10 pus cells, a few red blood cells and a few hyaline casts per high power field.

A roentgenogram of the abdomen showed enormous distention of the large intestine and cecum, but no small intestinal patters and no fluid levels. This finding again raised the question of a low obstruction with a competent ileocecal valve and a small barium sulfate enema was administered by Dr Joseph Peden, the barium passed promptly well across the transverse colon. Its administration was stopped for fear of increasing the pressure within the distended cecum. Fluoroscopic examination of the chest showed what appeared to be a

1915

nodule in the right lung base just above the diaphragm, a film showed an irregular area of infiltration of uncertain nature

On the return of the patient from the roentgen examination a nasal catheter was passed into the stomach and only 100 cc of light green fluid was obtained, continuous suction³ was started. One thousand cubic centimeters of Hartmann's solution was given as a hypodermoclysis and 1,500 cc of 5 per cent dextrose in physiologic solution of sodium chloride intravenously at the rate of 500 cc an hour. At 4 p m the patient looked much fresher and brighter the pulse rate was 90 respiration 35, blood pressure 195/95, temperature 99.6. Only 75 cc of greenish fluid had been recovered by suction from the stomach by this time. The patient was then considered to be a reasonable risk for operation. Our preoperative note at 4 p m states that there was practically no fluid in the stomach after two hours' suction. With the roentgen observations fever and blood picture it seemed certain that distention was due to an infectious process with paralytic ileus. Entire lack of localizing signs on physical examination left us faced with exploration without a more definite diagnosis but the very absence of such observations favored retrocecal appendicitis, probably perforated, less likely diagnoses were ovarian tumor on a twisted pedicle, Meckel's diverticulum, strangulated internal hernia and so on. A chest film showed an area of increased density that might be an early pneumonia but it was not of sufficient significance to postpone operation.

Operation—After morphine and ephedrine hypodermically, spinal analgesia was induced with 175 mg of procaine hydrochloride. An incision was made at the middle third of the right rectus muscle the latter being shelled out of its sheath, and fluid blood under tension welled out of the peritoneal cavity as soon as it was opened. Exploration of the pelvis revealed only an atrophic uterus with normal adnexa. It was estimated that there were 2 liters of fluid blood in the abdominal cavity and many clots. The exploring hand encountered several gallstones in the pelvis following which the incision was extended upward to the rib margin and the gallbladder was visualized. There was no sign of any localizing process around the gallbladder, on the under surface of which was a fairly clean, straight rent 3 cm long from which dark apparently venous, blood was slowly welling there was no distinct arterial spurting. The gallbladder wall was thin and the organ was of approximately normal size. Probably more than 100 small faceted stones were scattered around the peritoneum and a few remained in the gallbladder there was partial separation of the gallbladder from the liver bed and the latter was not bleeding. The rent in the gallbladder was sutured with a continuous suture in two rows, and a large Pezzar catheter was introduced through a small incision in the fundus into the gallbladder and the wall was inverted snugly around it with two rows of sutures. A gauze pack was placed around the gallbladder brought out at the upper angle of the incision, and walled off from the hollow viscera with a layer of gutta percha. The abdominal wall was then closed as a single layer with through and through sutures of silk worm gut.

Postoperative Course—A transfusion of 500 cc of blood was given immediately, and routine peritonitis care was instituted including inhalations of carbon dioxide and oxygen every hour. 3,000 cc of 5 per cent dextrose and saline solution was given intravenously at the rate of 300 cc an hour over night and the patient excreted 325 cc of urine. On the morning of the 12th the patient's condition was very satisfactory, the pulse was 110 respiration 24, blood pressure 148/82, temperature 100. There had been no nausea and the return from continuous suction of the stomach was negligible. The chest was negative to a limited examination. At noon the patient began to cough and became cyanotic, voiding involuntarily. At 4 p m the chest was full of coarse rales and resonance was impaired throughout the entire right lung, there was no change in the position of the heart. The pulse rate was 140 respiration 28, temperature 103. Roentgen examination showed cloudy infiltration and mottling throughout the entire right lung and questionable infiltration of the hilus area of the left lung these were considered to be signs of bronchial pneumonia. Bile was coming

through the Pezzar catheter at this time. The usual treatment with oxygen and digifolin was unavailing, and the patient died at 12 25 p m, February 13.

Autopsy—This was limited to the abdomen and was performed at once. The suture line around the Pezzar catheter in the gallbladder was intact, as was the suture line closing the tear in the gallbladder, and there was no sign of bleeding from either the liver bed or from the gallbladder itself. A few clots were found in the flanks and on the diaphragmatic surface of the liver. Liver, gallbladder, and common bile duct were removed *en masse* and taken to Dr I Y Olch in the surgical pathologic laboratory of the Washington University School of Medicine, who made the pathologic examination.

The material consisted of the liver and gallbladder removed at necropsy. A long Pezzar catheter was in the gallbladder and was held in place by a purse-string suture at the fundus. The gallbladder had been separated from its bed on the right and the quadrate lobes of the liver. Along the right margin of separation was a line of sutures holding together the gallbladder, where it was found at operation to be perforated into the free peritoneal cavity. This suture line appeared intact. The gallbladder measured 8 by 3 by 3 cm and contained no stones, although stones were said to have been present at operation. The serosa was rough, it was red, the walls were thickened to 5 mm and the mucosa was hemorrhagic and edematous. No stones were found on dissection of the valves of Heister and of the cystic duct. The hepatic duct was free of stones. The liver looked normal. The gross diagnosis was recent perforation of a gallbladder that was acutely inflamed and contained stones.

On microscopic examination a section showed a thick gallbladder wall which was markedly edematous. The mucosa was absent probably postmortem autolysis. Another section showed liver in which there was extensive central necrosis with considerable blood in the sinusoids in the midzonal areas.

The diagnosis was cholelithiasis, chronic cholecystitis.

COMMENT

The midzonal necrosis of the liver described microscopically was thought to be due to the terminal fever accompanying the fatal pneumonia. Since the gallbladder was not grossly thickened or edematous at operation the postmortem condition in the gallbladder was due, we believe, to the presence of the Pezzar catheter during the forty hours that elapsed from operation until death. It seems to us that vomiting associated with the onset of pain in the present illness, increased the intra-abdominal tension to such an extent that the thin wall of the gallbladder was pressed on its tightly packed content of sharply faceted stones with sufficient force to produce a tear through the wall and subsequent unchecked hemorrhage. An effort was made to dissect out the cystic artery in the surgical pathologic laboratory, but it proved to be so small that this was not practical. Its many branches were not located in the vicinity of the rent in the gallbladder.

CONTRAST STAIN FOR THE RAPID IDENTIFICATION OF TRICHOMONAS VAGINALIS

JAMES RAGLAN MILLER, M.D. HARTFORD, CONN.

The use of the hanging drop or wet smear under a cover glass for the identification of *Trichomonas vaginalis* occasionally offers difficulties when the organisms are few or when their motility is temporarily suspended. I have found that a drop of 0.1 per cent safranin is useful as a diluent for the pus that is to be examined. Not only the nuclear material but protoplasm also of the leukocytes rapidly takes safranin stain, whereas the *Trichomonas vaginalis* organism remains unstained and conspicuous as a clear object against a slightly pink background.

It is noticeable also that the safranin, at least in this dilution, does not interfere with the motility shown by *Trichomonas*, if anything, it appears to stimulate it. Under the low power it is often possible more quickly to pick out areas where the organisms are numerous, so that identification with the high power objective can be quickly effected.

Council on Pharmacy and Chemistry**REPORTS OF THE COUNCIL**

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH Secretary

EPHEDRITONE INHALANT-MASSEY'S NOT ACCEPTABLE FOR N N R

Under the name "Ephedritone Inhalant," the Massey Laboratories, Inc., Nashville, Tenn., presented for the Council's consideration a preparation stated to contain 1 per cent each of ephedrine and chlorbutanol in an aromatic base, proposed for use "in congested conditions of the mucous membranes." The aromatic base is stated to contain a "stabilized vegetable oil" the nature of which was not specified. The Council accepts no product the composition of which is not adequately declared. In this case this requirement is of special importance in view of the possible presence in the oil of aldehydes that may be incompatible with ephedrine.

In the submitted advertising occurs the statement

Clinical tests made by leading specialists prove that the synergistic effects of Ephedrine and Chlorotone give a prolonged contraction of capillaries and prolonged reduction of swollen turbinates without irritation.

The Council is not aware of any convincing evidence that there is synergistic action between the two drugs. Instead of the vague reference to tests by "leading specialists," the firm should submit such evidence if it is available.

Perhaps the chief objection to this product from the Council's point of view is the use of the coined proprietary name Ephedritone for an unoriginal mixture of well known drugs. Fundamentally this objection is based on the fact that such names are not informative to the physician who prescribes, their use creates a multiplicity of names for the same medicament. 'Ephedritone' also carries a therapeutic suggestion, a fact that considerably aggravates its offense to rational therapeutics. In practice it has been found that such names facilitate injudicious and harmful self medication by the public. The physician prescribes the mixture for a given condition, the name sticks easily in the patient's mind, and the next time he or a friend has an ailment that seems similar, another bottle is obtained at the drug store and unknown symptoms may go untreated or contraindicated treatment may be given to other existing symptoms.

Although it has been informed of the Council's objections to the product for more than a year, the firm has taken no steps to make it acceptable. The Council voted therefore to declare Ephedritone Inhalant Massey's unacceptable for inclusion in New and Nonofficial Remedies, and authorized publication of this report.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

SUPRARENIN (See New and Nonofficial Remedies, 1935, p 206)

The following dosage form has been accepted

Ampules Suprarenin Powder 0.05 Gm. Each ampule contains suprarenin bitartrate 0.091 Gm., equivalent to suprarenin 0.05 Gm.

NEODIARSENOL (See New and Nonofficial Remedies, 1935 p 78)

The following dosage form has been accepted

Acquarol 18 Gm. Ampoules

RABIES VACCINE (See New and Nonofficial Remedies, 1935 p 380)

United States Standard Products Company, Woodworth, Wis.

Rabies Vaccine (Killed Virus) Semple (U S S P Co.) (See New and Nonofficial Remedies 1935 p 384)—Also supplied in the form of a 25 per cent suspension of brain substance containing 0.5 per cent of phenol. Marketed in packages of seven and fourteen vials each containing a single dose (0.5 cc.)

NORMAL HORSE SERUM (See New and Nonofficial Remedies, 1935, p 364)

The National Drug Co., Philadelphia

Normal Horse Serum (See New and Nonofficial Remedies 1935 p 365)—Also marketed in packages of one 10 cc vial and in packages of one 100 cc double ended vial complete with intravenous outfit. One cc of a 10 per cent dilution is included with each package for determining sensitivity of the patient by scratch or intradermal test.

Committee on Foods**ACCEPTED FOODS**

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING Secretary

1 ALLERTON FARM BRAND EVAPORATED MILK**2 KOPPERS STORES BRAND EVAPORATED MILK**

Distributors—1 Pittsburgh Provision & Packing Company, Pittsburgh 2 Koppers Stores, Inc., Pittsburgh

Packer—Armour & Company, Chicago

Description—The procedure of evaporation and canning, and the analysis are essentially the same as for the usual evaporated milk (THE JOURNAL, April 16, 1932, p 1376)

CELLU BRAND SPINACH, WATER PACKED

Distributor—Chicago Dietetic Supply House, Inc., Chicago

Packer—Kings County Packing Company, Armona, Calif

Description—Canned spinach, packed in water

Manufacture—Spinach at the proper degree of maturity is trimmed, thoroughly washed, blanched, drained and packed in cans. The cans are filled with water, heated, sealed and processed.

Analysis (submitted by distributor)—

	per cent
Moisture	93.4
Total solids	6.6
Ash	0.8
Fat (ether extract)	0.4
Protein (N X 6.25)	2.1
Crude fiber	0.9
Starch (diastase method)	1.7
Carbohydrates other than crude fiber (by difference)	2.4

Calories—0.2 per gram 6 per ounce

Claims of Manufacturer—Choice quality spinach packed without added sugar or salt. For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

MEYENBERG ALL PURE BRAND EVAPORATED MILK

Manufacturer—Meyenberg Milk Products Company, Salinas, Calif

Description—Unsweetened, sterilized evaporated milk

Manufacture—Milk from farms under government supervision is inspected, filtered, evaporated, homogenized, cooled, standardized for milk-fat and total solids, automatically filled into cans, sealed and sterilized.

Analysis (submitted by manufacturer)—

	per cent
Moisture	73.4
Total solids	26.6
Ash	1.5
Fat (ether extract)	7.9
Protein (N X 6.38)	8.3
Lactose (by difference)	8.9

Calories—14 per gram 40 per ounce

Claims of Manufacturer—See announcement of acceptance of Evaporated Milk Association, Educational Advertising (THE JOURNAL, Dec 19, 1931, p 1890)

RADIOLOGIC SERVICE IN THE UNITED STATES

REPORT BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The names of 1,274 physicians specializing in radiology are included in this, the sixth publication of the Council's list. The type of service rendered is given opposite the name 'Radiology,' under "Type of Service," always includes short wave therapy, also known as "deep therapy." The asterisk (*) on "Roentgenology" indicates that short wave therapy is included.

The publication of this list in this issue completes the duty assigned to the Council of preparing a list of radiologists. This function is now being transferred to the American Board of Radiology, which was approved by the Council on Medical Education and Hospitals, Dec 9, 1935. Many radiologists did not apply to the Council in anticipation of the formation of the Board. Recent applicants have been referred to the Board. Therefore the list on the following pages contains few additions and changes.

The list of the Board's diplomates to Jan 1, 1936 appears in 'Radiology' for January 1936.

The Board will conduct examinations in May and September of the present year. Appointments for examination are made through Dr B R Kirklin, Secretary, American Board of Radiology, Rochester, Minn.

SENSITIVENESS AND RESISTANCE TO ROENTGEN RAYS OR RADIUM

Physicians who are not well versed in radiology often consider radiosensitiveness and radioresistance as absolute expressions. To them a tumor is either sensitive or resistant to irradiation, and intermediate gradations are not recognized. Experienced radiologists use these terms only in a relative sense. Just as different varieties of normal cells vary greatly in sensitiveness to roentgen rays or radium, tumors vary equally in this respect. It has been established that the radiosensitiveness of any tumor corresponds to that of the cells of which it is chiefly composed. The scale of radiosensitiveness of different varieties of neoplasms must, and does in fact correspond to the degree of sensitiveness of its essential cellular constituents. In other words, the scale of radiosensitiveness of different varieties of tumor corresponds to the scale of sensitiveness of the different varieties of normal cells.

The normal lymphocytes are the most sensitive of all cells to irradiation. Tumors composed mainly of lymphocytes are most sensitive to roentgen rays or radium. The sensitiveness of embryonal carcinoma of the kidney or testis is slightly less than that of lymphoid tumors. Next in relative sensitiveness comes endothelioma or endothelial myeloma of bone. At the opposite end of the scale of sensitiveness to irradiation must be placed tumors derived from nerve cells or from myxomatous tissue. In the case of a mixed tumor, sensitiveness to irradiation represents a composite of its cellular elements, when sensitive cells predominate, the degree of sensitiveness is greater than when the proportion of sensitive cells is small. Thus between maximum sensitiveness and maximum resistance there are numerous gradations. Therefore to speak or to write of a tumor as sensitive or resistant to irradiation, without qualification to indicate the grade or relative degree of these qualities, is to mislead others into assuming that a tumor is either 100 per cent sensitive or 100 per cent resistant. Just as a mixture of different proportions of red and white may yield innumerable intermediate shades of color, so many different

varieties of tumor exhibit varying degrees of sensitiveness or resistance according to the relative proportion of sensitive and resistant cells which they contain.

In estimating the relative sensitiveness of any tumor, two principal factors must be considered: the rate of regression and the scheme of irradiation. The significance of the first factor rests entirely on the second factor. One tumor may regress completely in two or three weeks, regression of another tumor may require two or three months, a third growth may not disappear completely, however prolonged the treatment may be, or may not be perceptibly influenced. Examples include lymphoblastoma, endothelioma of bone, osteogenic sarcoma and myxosarcoma.

The rate of regression of a new growth cannot well be compared with that of another unless the scheme of irradiation is approximately the same. This refers not only to the quantity and quality of rays to which the affected region has been exposed but also and perhaps even more to the arrangement of the fields of irradiation and the direction of the several beams of rays in relation to the tumor.

Another general statement often made is that neoplasms corresponding to grades 3 and 4 of Broders' scale of malignancy are radiosensitive, while neoplasms corresponding to grades 1 and 2 are resistant to irradiation. This represents a conclusion drawn from purely pathologic premises, its validity is at least doubtful. It represents a half truth which takes into account only a part of the equation. In this connection it is essential to remember that histopathologic structure and cellular radiosensitiveness are different bases which do not necessarily have anything in common. The one rests on the visual appearance of cells and the architectural arrangement of tissues, while the other rests on the innate sensitiveness of cells to roentgen rays or radium. In a general way it is true that the more malignant the tumor the more sensitive it is likely to be, but to deduce that only tumors with a malignancy corresponding to grades 3 and 4 of Broders' scale should be irradiated is to draw altogether too broad a conclusion.

FIRST AID TREATMENT OF FRACTURES

The emergency treatment of fractures of the long bones has become a problem of major importance. Scattered along the highways of the nation each year are more than a million persons injured by automobile accidents, and in the homes of the nation there are more than four million additional persons injured. Many of these are suffering from fractures of the long bones. About 300,000 fractures of the extremities occur annually in this country. In comparison with the number of injured in the American forces during the World War, the annual number of peace time injuries is gigantic. The first aid treatment of this vast number of injured persons, particularly those who have fractured bones, will largely determine in many cases the amount of pain, the length of their stay in the hospital

and to some extent whether or not they are permanently disabled. The first attendant to practically all these injured persons naturally will be laymen untrained in the care of fractures. Their first thought will be to lift and carry the victim, with perhaps his broken extremity dangling, to some place more comfortable than the roadside. As regards the eventual result to fractured limbs, this is the worst thing that could be done. The immediate effects will be additional injury by the jagged bones to nerves, blood vessels and muscles. The broken bones may thus be forced through the skin, creating a compound fracture and tremendously increasing the risk of infection and the danger to life. Injured persons with broken bones should first have a splint properly applied to the extremity before they are moved.

The Cooperative Committee on Fractures of the Section on Surgery, General and Abdominal and the Section on Orthopedic Surgery of the American Medical Association has prepared in cooperation with the Department of Scientific Exhibit a Primer on Fractures in which the principles of the modern treatment of fractures are illustrated and discussed. The Cooperative Committee on Fractures also will reestablish at the Kansas City session of the American Medical Association in May the fracture exhibit, which for several years attracted the attention of thousands of physicians in attendance at the annual meetings.

Proper instruction in the first aid treatment of fractures is of increasing importance. A campaign of instruction is under way throughout the country by such organizations as the Red Cross, the Girl and Boy Scouts, nurses organizations and many large industrial groups. The leadership in the teaching of first aid is naturally in the medical profession. Medical practitioners must therefore become proficient in giving and teaching first aid. Medical schools are insisting and the groups established for graduate instruction must demand that students possess the ability to apply emergency fixed traction splints. The teaching of first aid today is different from the old-fashioned attempts to teach the simple application of a folded handkerchief bandage. Cities are passing ordinances to require ambulances, police cars and other conveyances to carry first aid splints.

An official history of the war¹ said

It has always been recognized that the fixation of the broken bone at the earliest possible moment after the injury is important but it was not until 1915 that it became clearly recognized how much the subsequent satisfactory progress of any case of gunshot fracture depended on efficient splinting prior to transport. The appreciation of this fact was chiefly due to the demonstration afforded by the use of the Thomas knee-splint in the treatment of fractures of the femur. Fractures of this class were in the early days of the war, fixed in the forward area by some splint of the long outside type. Mortality among patients so treated was extraordinarily high and those cases which recovered were almost all subject to severe infections and a prolonged convalescence. After the general introduction in the forward areas of the Thomas splint for the treatment of this fracture the improvement in results was too great not

to attract attention. Apart from any advance which had been effected in wound treatment in general, it was clearly shown that an apparatus which fixed a fracture was able largely to prevent shock and to reduce the incidence of infection in the wound.

According to Dr. Kellogg Speed, chairman of the Cooperative Committee on Fractures the World War¹ furnished proof of the reduction in mortality in major open fractures from 80 per cent to 20 per cent, with the help of this means of transportation. The principles of the Thomas splint remain sound and some modifications have also been found acceptable. The day will probably come when every public vehicle and every doctor's car will carry the proper splints for fixed traction in first aid transportation.

COPPER AND PIGMENTATION OF SKIN AND HAIR

Pronounced changes occur in the color of the fur of black or "hooded" rats that consume an exclusive milk diet low in copper.¹ A progressive decrease in the amount of pigmentation occurred as the dietary regimen continued until finally the coat became a silvery gray. The administration of iron to the animals had no effect on the condition, but the feeding of a small amount of copper promoted a prompt restoration of the normal color to the fur. Almost simultaneously, another investigator demonstrated by actual analyses that the copper content of the skin of black rats and rabbits usually exceeded that of otherwise comparable white animals. Further studies suggested that copper might serve as a catalyst in the formation of pigment. Copper it was shown, markedly accelerated the oxidation of dopa '1-3-4-dihydroxyphenylalanine by dopa oxidase, an enzyme present in the skin of young animals forming a dark pigment. Even in the absence of the enzyme the oxidation was catalyzed by copper to some extent.

Recent investigations have confirmed and extended these observations. A Japanese investigator² has demonstrated that the copper content of black skin and hair is somewhat greater than that of brown skin and hair which in turn exceeds white skin and hair in this respect. This relationship held even in instances in which skin and hair varying in degree of pigmentation were taken from different areas of the same animal. It was also found that amounts of copper as small as 0.05 microgram catalyzed the *in vitro* oxidation of dopa to a dark colored pigment.

Gorter⁴ likewise relates copper to the pigmentation of skin and hair. Striking depigmentation of the fur

of cats, rabbits and rats was produced by dietary means and the condition was specifically cured by copper. A number of other inorganic elements, tested either alone or in various combinations, and certain vitamins were inert as remedial agents. While further work must be done before conclusions are drawn, these observations strongly suggest that copper may be related, perhaps as a catalyst, to the formation of pigment in the skin and hair of mammals.

Current Comment

CERTIFICATION OF RADIOLOGISTS

At the Minneapolis session of the American Medical Association in 1928 the House of Delegates assigned to the Council on Medical Education and Hospitals the work of preparing a list of acceptable radiologic laboratories and departments of radiology. This was in response to requests from the sections on radiology of several medical societies for a supervision similar to that already established over clinical laboratories. Since greatest emphasis was placed on the qualifications of radiologists in charge of such laboratories, "Essentials for Admission to List of Physicians Specializing in Radiology" were formulated and were adopted by the House of Delegates. This provided a basis for the Council's list of radiologists. The list was first published in *THE JOURNAL* in 1931, the sixth and final publication of the list containing 1286 names, appears elsewhere in this issue. The local advisory committees of radiologists played an important part in developing the Council's list. The regular publication of the list since 1931 has been a great influence in advancing the specialty of radiology to the position in scientific medicine it now occupies. Physicians everywhere have been encouraged to refer their work to medical graduates recognized as specialists in this field. There is evidence that independent lay practitioners have been effectively curbed. The principles proclaimed in the "Essentials for Admission to List of Physicians Specializing in Radiology" and otherwise have been an educational force, and they have confirmed the fact that the practice of radiology is the practice of medicine. The American Board of Radiology, which was established in 1933, conducted its first examinations at Cleveland in 1934. The board at present is composed of the following doctors of medicine: H. K. Pancoast, Philadelphia, president; A. C. Christie, Washington, D. C., vice president; E. C. Ernst, St. Louis; G. W. Holmes, Boston; E. L. Jenkinson, Chicago; L. C. Kinney, San Diego; Calif., W. F. Manges, Philadelphia; L. J. Menville, New Orleans; J. W. Pierson, Baltimore; L. R. Sante, St. Louis; Henry Schmitz, Chicago; Albert Soiland, Los Angeles; M. C. Sosman, Boston; R. H. Stevens, Detroit; and B. R. Kirklin, Rochester, Minn., secretary-treasurer, to whom applications should be directed. The Council on Medical Education and Hospitals of the American Medical Association officially extended its recognition to this board, Dec. 9, 1935.

Therefore the list of diplomates of the American Board of Radiology will henceforth take the place of the Council's list of radiologists.

DETECTION OF ENDEMIC FLUOROSIS

The remarkable development of knowledge concerning the role of fluorine in causing mottled enamel has been previously discussed in these columns.¹ Definite evidence now exists associating the presence of fluoride in drinking water with the endemic hypoplasia of the permanent teeth known as mottled enamel. It is important therefore to determine what constitutes a non-injurious amount of fluoride in a domestic water supply. Any attempts to arrest the further development of this disease are obviously based on definite information concerning the permissible maximum or minimum threshold values for the fluorine content of the water regularly consumed. For public health purposes it is important to establish an arbitrary minimal threshold of fluoride concentration in domestic water supplies so that data obtained in various localities may be related to this norm. The minimal threshold of fluoride concentration has been defined by the United States Public Health Service laboratories as the highest concentration of fluoride incapable of producing a definite degree of mottled enamel in as much as 10 per cent of the group examined.² The group studied should consist of at least twenty-five children and is restricted, in general, to children 9 years of age or older who, since birth, have continuously used the water under investigation for both drinking and cooking. A community is given a "negative" mottled enamel index when less than 10 per cent of the children show "very mild" or more severe types of mottled enamel. With these useful criteria, studies have already been made of endemic fluorosis in eleven cities, six where mottled enamel was known to be endemic and five in which comparable conditions existed but without evidence of the typical dental defects in the population and which served as "controls." Owing to the fluctuating content of fluoride in certain municipal water supplies, caution should be exercised in correlating clinical observations with a single chemical determination of fluoride in the water. Furthermore, care must be taken in obtaining the full details of the case histories, as continuous residence in the suspected regions is of great importance in eliciting the abnormalities in the dental structures. On the basis of the foregoing combination of criteria, two municipalities in Illinois with a mean annual fluoride content of 1.7 and 1.8 parts per million in the water, and one city in Colorado with 2.5 parts per million were given a mottled enamel index of "slight," whereas one city in Colorado with 0.6 part per million was listed as "negative." The interesting results and relationships derived from these studies and the application of this method of approach to other regions of this country will undoubtedly provide valuable information regarding endemic fluorosis and indicate the localities in which it is necessary to remove toxic quantities of fluorides from the drinking water.

Association News

RADIO BROADCASTS

The American Medical Association broadcasts over WEAF, the Red network instead of the Blue, as formerly, and certain additional stations of the National Broadcasting Company at 5 p m eastern standard time (4 o'clock central standard time, 3 o'clock mountain time 2 o'clock Pacific time) each Tuesday, presenting a dramatized program with incidental music under the general theme of "Medical Emergencies and How They Are Met" The title of the program is "Your Health" The program is recognizable by a musical salutation through which the voice of the announcer offers the toast "Ladies and gentlemen your health" The theme of the program is repeated each week in the opening announcement, which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community, day and night for the promotion of the health of the people Each program will include a brief talk dealing with the central theme of the individual broadcast

Red Network¹—The stations on the Red network of the National Broadcasting Company are WEAF, WEEL, WTIC, WJAR, WTAG, WCSH, KYW, WFBR, WRC, WGY, WBEN, WCAE, WTAM, WWJ, WMAQ, KSD, WHO, WOW, WDAF

Pacific Network¹—The stations on the Pacific network are KGO, KPO, KFI, KGW, KOMO, KHQ, KFSD, KTAR

institution Whittier High School, Antelope Valley High School and Norwalk Grammar School were closed

Society News—Dr Roger Anderson, Seattle, will address the Alameda County Medical Association, March 5, on "Fractures of the Upper and Lower Extremities" A symposium on diseases of the thyroid gland was presented before the society, February 17, by Drs Paul P E Michael, George E Nesche and Frank H Bowles Oakland —Dr Arthur B Cecil, Los Angeles, addressed the San Diego County Medical Society, February 11, on "Deformities of the Male Urethra"

CONNECTICUT

Dr Phelps Retires as Professor—Dr Winthrop M Phelps will retire in June from Yale University School of Medicine, New Haven, as professor of orthopedic surgery and become a clinical professor, devoting only part time to the medical school, the New York Times reported February 8 Dr Phelps graduated from Johns Hopkins University School of Medicine, Baltimore, in 1920 He has been a professor at Yale since 1932 and a member of the faculty since 1925

Society News—Dr Albert Buck superintendent of New Haven Hospital, was elected president of the Connecticut Hospital Association at the recent annual meeting —Dr Bernardo A Houssay, professor of physiology and director of the Institute of Physiology, National University of Buenos Aires, addressed a special meeting of the Yale Medical Society, New Haven, January 18, on "The Hypophysis and Carbohydrate Metabolism" Speakers before the society, February 12, included Charles-Edward A Winslow, Dr P H, Lovie P Herrington Jr, Ph D, and A P Gage on "Measurement of Thermal Interchanges Between the Body and Its Environment by Differential Calorimetry" Drs Monroe D Eaton, "The Nature of Diphtheria Toxin", Ashley W Oughterson "Spinal Cord Level of Preganglionic Fibers in Relation to Horner's Syndrome," and Edwin F Gildea and Evelyn B Man, Ph D, "The Relation Between Blood Lipoids and Body Build"

DISTRICT OF COLUMBIA

Medical Bills in Congress—S 3514 has been reported to the Senate, with amendment proposing to regulate the manufacture, dispensing, sale and possession of narcotic drugs in the District of Columbia (S Rept 1538) H R 8437 has been reported to the Senate, without amendment, directing the Commission on Licensure to Practice the Healing Art in the District of Columbia to issue a license to Dr Arthur B Walker

Health at Washington—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended February 8, indicate that the highest mortality rate (231) was for Washington and for the group of cities as a whole, 134 The mortality rate for Washington for the corresponding period last year was 164, and for the group of cities, 131 The annual rate for eighty-six cities for the six weeks of 1936 was 134 as against a rate of 131 for the corresponding period of the previous year Caution should be used in the interpretation of these weekly figures, as they fluctuate widely The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate

Society News—The Medical Society of the District of Columbia was addressed, February 12 by Drs Panigotes S Constantinople on "Chronic Otitis Media", Harry S Bernton "The Common Cold and Asthma," and Elizabeth Parker and Harry S Douglas, "Acromegaly" A symposium on cardiac pain was presented before the society, February 19, by Drs Louis Hamman, Baltimore, Earl A Martin and Joseph Duerksen Stout Dr Alfred L Abrams will present a paper February 26, entitled "Epidemic Poliomyelitis in Washington Clinical Survey with Emphasis on Diagnostic Features," and Dr Earl B McKinley, "The Geography of Disease"—Dr Robert A Wilson Brooklyn, discussed "A Study of the Asphyxia and Early Respirations of the New-Born" before the Washington Gynecological Society, January 25

ILLINOIS

Society News—Speakers at the quarterly meeting of the Henry County Medical Society in Cambridge, February 13 were Drs Ford K Hick and Charles M McKenna, both of Chicago, on pneumonia and prostatitis, respectively —At a meeting of the Perry County Medical Society in DuQuoin, February 6, Drs Quitman U Newell and Oswald P J Falk, St Louis, discussed cancer and cardiovascular diseases —Dr Frederick G Dvas Chicago, discussed gonorrhea before the DuPage County Medical Society in Elmhurst, January 15

Chicago

Dr Abt Donates Library to Medical School—Dr Isaac A. Abt, professor of pediatrics, Northwestern University School of Medicine, has presented his library on the diseases of children, collected over a period of forty years, to Northwestern. The collection comprises 3,500 volumes and is valued at approximately \$25,000.

Chicago Medical Society Endorses Dr. Humiston—The council of the Chicago Medical Society, February 11, adopted a resolution endorsing Dr. Charles E. Humiston as candidate for president-elect of the American Medical Association. The resolution reads as follows:

WHEREAS The Illinois State Medical Society through its Council by unanimous vote has endorsed Dr. Charles E. Humiston as candidate for President Elect of the American Medical Association and instructed its Delegates to urge his election at the Kansas City meeting therefore be it

Resolved By the Council of the Chicago Medical Society in regular meeting assembled that said action of the Illinois State Medical Society in recognizing the superior qualifications of our distinguished fellow member for the high office of President of the American Medical Association be and hereby is commended approved and endorsed.

Supreme Court Holds Corporate Practice of Medicine Illegal—The Supreme Court of Illinois, February 14, in *People v. United Medical Service Inc.* held that a corporation cannot legally practice medicine in Illinois even though it attempts to do so through physician employees. It accordingly affirmed a judgment rendered by Judge M. L. McKinley of the Superior Court, Cook County, March 1935, ousting the United Medical Service Corporation from the franchise occupation and business of engaging in the diagnosis and treatment of human ailments. According to the *Chicago Tribune*, February 15, an attempt will be made to reorganize the corporation on a partnership basis, in the hope of avoiding legal difficulties. It is intimated, however, that before attempting such a reorganization the corporation may ask for a rehearing from the Supreme Court of Illinois and appeal if possible, to the Supreme Court of the United States.

Society News—Speakers before the Chicago Medical Society, February 8, were Drs. Harry Culver on 'Borderline Problems in Diagnostic Urology', Joseph S. Eisenstaedt

'Bladder Tumors', and Herman L. Kretschmer, 'Transurethral Resection in Various Types of Bladder-Neck Obstruction'.—At a meeting of the Chicago Pathological Society, February 10, Francis B. Gordon and Dan H. Campbell, department of bacteriology, University of Chicago, among others were the speakers on 'Active and Passive Immunity in Experimental Poliomyelitis and Antigenic Polysaccharides from Helminths', respectively.—The Chicago Roentgen Society was addressed, February 13, by Drs. Alfred E. Jones and Philip Rosenblum on 'Foreign Bodies in the Genito-Urinary Tract', and Warren W. Furey, 'Intestinal Obstruction as a Roentgenological Problem'.—Dr. Robert D. Schrock, Omaha, discussed 'Treatment of Sprengel's Deformity', and Immediate Bone Grafting Following Resection of Benign Bone Tumors' at a meeting of the Chicago Orthopedic Society, February 14. Dr. Samuel J. Lang discussed 'The Mechanics of the Back and Its Relation to Backache'.—Among others, Dr. Edward V. L. Brown addressed the Chicago Ophthalmological Society, February 17, on 'The Apparent Increase of Hyperopia Before Nine Years of Age'.—A symposium on contact dermatitis was presented before the Chicago Society of Allergy, February 17, by Drs. Samuel J. Zakon, Chicago; Louis A. Brunsting, Rochester, Minn.; and Carliss Malone Stroud, St. Louis.

INDIANA

Society News—Dr. James B. Shoemaker, Miami, addressed the Miami County Medical Society in Peru, January 31, on 'Protein Therapy'.—Speakers before the Madison County Medical Society, Anderson, February 17, included Drs. Sam W. Litzenberger, on 'Hormone Treatment of Prostatic Hypertrophy', Otis A. Kopp, 'Over-treatment of Syphilis', Rex W. Dixon, 'Systemic Allergic Reactions', and Archie D. Erehart, 'Sinus Infections or Nasal Allergy'.

State Board Re-elected—The Indiana State Board of Medical Registration and Examination re-elected all officers at the annual meeting in January. Dr. Jesse W. Bowers, Fort Wayne, president; Dr. Leslie C. Sammons, Shelbyville, vice president; Dr. William R. Davidson, Evansville, secretary; and Cecil J. Van Tilburg, D.C., Indianapolis, treasurer. Other members of the board are E. O. Peterson, D.O., La Porte; Dr. Norris E. Harold, Indianapolis; and Dr. Franklin S. Crockett, Lafayette.

New Medical School Building—The *Journal of the Indiana State Medical Association* announces that a new medical school building will be constructed on the Bloomington campus of Indiana University to be erected as a federal project

at the university at a cost of \$471,000. It will be named the James William Tesler building in honor of the president of the board of trustees of the university, in recognition of his services as a member of the board since 1902 and president since 1919.

MARYLAND

Curative Workshop—Occupational therapy has recently been made available to outpatients at the University Hospital, University of Maryland, Baltimore, through the opening in the dispensary of a curative workshop, under the auspices of the Junior League of Baltimore. Suitable equipment has been installed. The department is under the direction of Miss Sue Hurt, a graduate of the Philadelphia School of Occupational Therapy.

Dr. Lomas Honored—A banquet was held in honor of Dr. Arthur J. Lomas, superintendent of the University Hospital, Baltimore, at the Southern Hotel, January 7, as a tribute to his efforts in erecting the new hospital building. Dr. William H. Toulson acted as toastmaster. The speakers included Mr. H. C. Byrd, acting president of the University of Maryland, Dr. James M. H. Rowland, dean of the medical school, and Dr. Arthur M. Shipley, who presented Dr. Lomas with a token of esteem.

Memorial to Dr. Ruhrah—A memorial room was opened in the building of the Medical and Surgical Faculty of Maryland, January 21, in honor of the late Dr. John Ruhrah, Baltimore. The room was furnished by friends of Dr. Ruhrah, principally outside the medical profession, and it is hoped ultimately to make this room a replica of the one in which he lived and worked for the last twenty-five years of his life. Many of his own books have been placed in the room, which will be formally dedicated at the annual meeting of the faculty in April. The opening of the room was a feature of the meeting of the Osler Historical Society. Dr. Sanford V. Larkey, librarian, Welch Medical Library, Johns Hopkins University, spoke on 'Children and Witches', and Dr. John Rathbone Oliver presented 'An Unpublished Autograph Letter of Dr. John Crawford'. Dr. Ruhrah, who died March 10, 1935, provided in his will that most of his estate will eventually go to the faculty. Among other positions he was professor of pediatrics at the University of Maryland School of Medicine, president of the American Pediatric Society, American Academy of Pediatrics, and the Medical and Surgical Faculty of Maryland, president and secretary-treasurer of the Medical Library Association and president of the Research Society of the Osler Historical Society.

MASSACHUSETTS

Personal—A testimonial dinner was given to Dr. Henry M. Pollock, superintendent Massachusetts Memorial Hospitals, at the Parker House, January 30, by about 300 associates and friends of the Massachusetts Memorial Hospitals. Dr. Pollock is an associate commissioner of the department of mental diseases.—Drs. Austen T. Riggs and Charles H. Kimberly have been appointed to the staff of the William College health department, Williamstown.

British Physician to Lecture at Harvard—Sir Fredrick Gowland Hopkins, Sir William Dunn, professor of biochemistry at the University of Cambridge, England, and since 1914 professor of biochemistry, has been appointed to the Harvard faculty for the academic year beginning next September. As the Edward K. Dunham annual lecturer, he will deliver a series of lectures in the medical school. The Dunham foundation was established in 1923 for the promotion of the medical sciences. Holders of the lectureship are drawn chiefly from among the leaders of foreign medical research. The Nobel Prize in medicine was conferred on Sir Frederick in 1929.

Free Public Lectures—The faculty of Harvard Medical School began a series of free public lectures on medical subjects, January 5, when Dr. Daniel F. Jones discussed cancer. Lectures to be given in the future will be:

Dr. Henry Jackson Jr., February 23, 'Role of the White Blood Cells in Health and Disease';
Dr. Reginald Fitz and Dr. Elliott C. Cutler, March 1, 'Appendicitis';
Dr. William B. Castle, March 8, 'Vitamins';
Dr. Hallowell Davis, March 15, 'Hearing and Its Conservation';
Dr. Herbert L. Lombard, March 22, 'Chronic Disease at the Cross Roads'.

Other lectures in the series were given by Drs. John H. Bliss, 'Cosmetics—Safe and Dangerous'; Harold C. Stuart, 'Prevention of Infectious Diseases'; William L. Aycock, 'Infantile Paralysis'; Leroy M. S. Miner, 'Prevention and Treatment of Physical Diseases of the Mouth'; Francis C. Hall, 'Gout and Allied Conditions'; and William H. Robey, 'The Prospect of Keeping a Good Heart'.

MICHIGAN

State Society Night—Several county medical societies in Michigan have adopted the plan of designating one of their meetings "state society night" when officers of the state society are guests of honor and participate in the program. The Jackson County Medical Society devoted its meeting January 21, to this program, Muskegon County, January 31, and Genesee County, February 19. Wayne County plans its "state society night" for some time in March.

Graduate Conferences—Graduate conferences are being held each Wednesday morning during February at the Herman Kiefer Hospital, Detroit, under the auspices of the joint committee of the Wayne County Medical Society, the Detroit Tuberculosis Sanatorium and the department of health. Topics have been the pathology of tuberculosis and scarlet fever, February 5, preventive measures in tuberculosis and whooping cough, February 12, diagnosis (childhood and adult tuberculosis) and diphtheria, February 19. Differential diagnosis of tuberculosis and anterior poliomyelitis will be the subject, February 26.

Personal—Dr Vladimir K Volk has resigned as deputy health commissioner of Oakland County to become health officer of Saginaw County, he is a past president of the Oakland County Public Health Association. A farewell dinner was given in his honor, January 29.—Dr Howard H Cummings, Ann Arbor, has been made assistant director of graduate medical education at the University of Michigan Medical School, Ann Arbor.—A testimonial dinner was given in honor of Dr Arthur O Hart, St Johns, January 21, by members of the staff of Clinton Memorial Hospital and others. An inscribed scroll was presented to Dr Hart expressing appreciation of his many years' service in the community.

MINNESOTA

Barber Wanted for Forgery—Olaf Edwardson, a barber is wanted by the Minneapolis police for forgery according to *Minnesota Medicine*. He is said to have imposed on a number of physicians throughout the state. He is described as 40 years of age, 5 feet 7 inches tall, weighing 155 pounds, he has medium dark chestnut hair, medium dark blue eyes, medium complexion, is bald and is of Norwegian descent.

Dr Mann to Give Judd Lecture—The third annual lecture in the E Starr Judd Lectureship in Surgery, established at the University of Minnesota by the late Dr Judd, will be given by Dr Frank C Mann, professor of pathologic surgery and experimental physiology, Mayo Foundation, March 17, in the Music Auditorium on the university campus in Minneapolis. The lecture will be entitled "Hepatic Physiology and Pathology from the Surgical Viewpoint. A Review of Experimental Investigations."

Society News—Dr Frank H Lahey, Boston, addressed the Minneapolis Surgical Society, February 6, at its fourteenth annual foundation dinner, his subject was "The Surgery of Carcinoma of the Colon and Rectum." Honorary membership was given to Drs William J and Charles H Mayo, Rochester, at this meeting.—Dr Robert D Mussey, Rochester, presented a paper before the Minnesota Academy of Medicine in St Paul, February 12, on "Relation of Retinal Changes to the Severity of the Acute Toxic Hypertensive Syndrome of Pregnancy," and Dr Arthur W Ide, Rupture of the Bowel from Compressed Air.—The Minnesota Hospital Association will hold its annual session at the Lowry Hotel, St Paul, May 14-16.—Dr Charles H Watkins, Rochester, addressed the annual meeting of the Winona County Medical Society in January on "Diagnosis and Treatment of Anemia."

MISSISSIPPI

Bills Introduced—S 223 and H 213 propose to create a state hospital commission to allocate and disburse such funds as may be appropriated by the state for the hospitalization of indigent sick. This commission is to be authorized to prescribe the conditions under which hospitals may receive state appropriations and to regulate the operation of such hospitals.

NEBRASKA

Society News—Dr Robert S Dimmore, Jr, Cleveland, gave an address before the Omaha Douglas County Medical Society, Omaha, February 11, entitled "Rescue of the Thyroid Problem." At a joint meeting of the society with the Omaha District Dental Society, February 25, speakers will be Arthur C Wherry, DDS, Salt Lake City, on "A Recent Study of Health Insurance in Europe," and Mr M C Smith, Curtis, executive secretary of the Nebraska State Medical Association,

on "The Future of the Practice of Medicine."—The third councilor district of the Nebraska State Medical Association held a meeting in Beatrice, January 23, with the following speakers: Dr Abram E Bennett, Omaha, "Present Status of Fever Therapy," Dr Ernest L MacQuiddy, Omaha, "Mold Simulating Common Infections," Dr Earl C Sage, Omaha, gave a lecture on "The Mechanism of Labor."—Dr Bert W Pyle discussed fractures at a meeting of the Dawson County Medical Society, Gothenburg, January 6.—Dr Leo J Hombach, North Platte, addressed the Lincoln County Medical Society, North Platte, January 9, on "Sinus Infections."—The Garden Keith Perkins Counties Medical Society was recently organized with Dr Firman M Bell, Grant, as president and Herbert A Blackstone, Lowell, secretary.

NEW YORK

Medal in Ophthalmology—The University of Buffalo gold medal is awarded annually to the author of a work in ophthalmology. Details may be obtained from Dr Harold W Cowper, 543 Franklin Street, Buffalo.

Society News—Dr Alexander Marble, Boston, addressed the Medical Society of the County of Westchester, White Plains, February 18, on "Practical Points in the Treatment of Diabetes in Hospital and Home."—Dr Edgar M Neptune, Syracuse, among others, addressed the Onondaga Medical Society, February 4, on carcinoma of the colon.—Dr Josephine B Neal, New York, addressed the Medical Society of the County of Nassau, January 28, on "Diagnosis and Treatment of Meningococcic Meningitis."

Bills Introduced—S 867, to amend the pharmacy practice act, proposes that the provisions of the act shall not apply "to the manufacture of proprietary medicines except those which are poisonous, deleterious and/or habit forming." S 829 proposes to grant to physicians, nurses and hospitals supported in whole or in part by charity, treating persons injured through the fault of others, liens on any judgments, settlements or compromises obtained by the injured persons by reason of their injuries. S 830 and A 963 propose to accord to hospitals supported in whole or in part by charity and treating persons injured through the fault of others liens on all judgments, settlements or compromises accruing to the injured persons by reason of their injuries.

New York City

Afternoon Lectures at the Academy—The series of Friday afternoon lectures at the New York Academy of Lectures will be as follows for the remainder of the season:

Dr Irving S Wright, "Diagnosis and Treatment of Peripheral Vascular Disease," March 6.	
Dr Nathan Rosenthal, "Hematology, Ethology,"	Special Reference to
Dr Foster Kennedy, "Central Nervous System,"	of Syphilis of the
Dr Abraham I Garbat, "Ambulatory Treatment of Peptic Ulcer,"	
March 27.	
Dr Gregory Schwartzman, "Recent Advances in Treatment of Bacterial Infections,"	April 3.

Chest Examinations of School Children—Roentgenograms will be taken of students in the fourth, fifth, sixth and seventh terms of the twenty-two high schools in Brooklyn in a joint undertaking by the New York City departments of education and health, the Medical Society of the County of Kings and the Brooklyn Tuberculosis and Health Association. About 60,000 pupils are registered in these groups. New Utrecht High School has been tentatively selected as the institution where the first roentgen examinations will be made, February 24. It will take about three months to complete them. The rapid x-ray survey method will be used and parents will be asked to pay a nominal sum of \$1 for the examinations. This fee covers the taking of the roentgenogram, interpretation by technicians designated by the county medical society, and a report of the results to the family physician in all cases in which medical care and treatment are needed.

Society News—A symposium on "The Etiology of Neoplasms" was presented at a joint meeting of the New York Pathological Society and the section of medicine of the New York Academy of Medicine, February 18, by Clara J Lynch, PhD, and Drs Francis Carter Wood and James B Murphy.—Drs Frederic E B Foley, St Paul, and Cyril K Church, addressed the section of genito-urinary surgery of the New York Academy of Medicine, February 19, on "A New Operation for Stricture at the Ureteropelvic Junction" and "Nephropexy. Analysis of Palliative and Operative Treatment in 266 Cases" respectively. At a meeting of the section of gynecology and obstetrics, February 25, speakers will be Drs John Mann, Toronto, on "Mechanical Principles in the Management of Occipitoposterior Positions," Charles O McCormick, Indian-

apolis, "Analgesia in Labor A Modified Gwathmey Technique," and Anthony Wollner, "A Preliminary Study of the Histologic Changes in the Human Cervical Mucosa."—Drs Stella S Bradford, Montclair, N J, and Heinrich F Wolf presented papers before the New York Physical Therapy Society, February 5, on "Exercise in the Treatment of Arthritis" and "Methods of Reeducation in Neurologic Conditions" respectively.—The New York Heart Association held a scientific meeting, January 28, with Drs William S McCann, Rochester, and Minnie Jane Sands Robb, Syracuse as speakers on "Cardiac Disorders in Chronic Pulmonary Disease" and "Studies of Cardiac Conduction" respectively

OHIO

Yellow Fever Volunteer Dies—Levi E Folk, Columbus, a volunteer in the group of yellow fever experiments conducted in Cuba by the U S Army Commission under Major Walter Reed, in 1900-1902, died February 8 after a long illness, aged 66. Folk, a private in the hospital corps, volunteered to be bitten by infected mosquitoes and was taken with yellow fever Jan 23, 1901. Folk was one of several volunteers who received gold medals and pensions of \$125 per month authorized by Congress in 1929. The medals were presented in 1931 (THE JOURNAL, Dec 5, 1931, p 1718)

Society News—Dr Marion A Blankenhorn, Cincinnati, addressed the Clinton County Medical Society, Wilmington, January 8, on "General Aspects of Deficiency Diseases."—Drs Ralph Deming, Paul M Holmes and William A Neill, Toledo, addressed the Sandusky County Medical Association, Green Springs, January 30, on tuberculosis.—Dr Albert Graeme Mitchell, Cincinnati, discussed "Nutritional Requirements and How to Fulfill Them" at a joint meeting of the Miami and Shelby County Medical Societies in Troy, January 2.—Dr Chesterfield J Holley, Wheeling, W Va, addressed the Guernsey County Medical Society, Cambridge, January 2, on "Diagnosis of Carcinoma of the Colon."—Dr George I Nelson, Columbus, spoke on pneumonia at a meeting of the Hempstead Academy of Medicine, Portsmouth, January 13.—Dr Albert C Furstenberg, Ann Arbor, Mich, addressed the Columbus Academy of Medicine, January 6, on "Acute Infection of the Mouth, Throat and Neck."—Dr M Herbert Barker, Chicago, addressed the Montgomery County Medical Society, Dayton, February 21, on pneumonia.—Dr Frederick A Collier, Ann Arbor, Mich, addressed the Summit County Medical Society, February 4, on "Water Balance in Surgical Patients." Dr Collier also addressed the Cleveland Academy of Medicine, February 21, on "Water Balance and Dehydration in the Sick Patient."

PENNSYLVANIA

County Secretary for Forty Years—Dr Anthony F Myers, Blooming Glen, was guest of honor at a dinner at Doylestown, recently, celebrating his fiftieth anniversary in the practice of medicine. Dr Myers, who is 80 years old, has been secretary of the Bucks County Medical Society for forty years. It is reported. Speakers at the dinner included Drs Frank Lehman and James Frederic Wagner, Bristol, Henry I Klopp, Allentown, and Edgar S Buyers, Norristown. Dr Harvey Doyle Webb, Bristol, presided.

Philadelphia

Personal—Dr Sigmund S Greenbaum, associate professor of dermatology and syphilology, University of Pennsylvania Graduate School of Medicine, has been appointed professor in the department. Dr Greenbaum, a graduate of Jefferson Medical College, is dermatologist at Mount Sinai Hospital.

Society News—Drs James P O'Hare, Boston, and Dana W Athley, New York, addressed the Philadelphia County Medical Society, February 12, on chronic glomerular nephritis and on nephrosis. At a meeting February 19 speakers were Drs Seth A Brumm, on "Immunization Following Electrocoagulation of Tonsils", Seymour DeWitt Ludlum, "Changes in the Globulin Picture Following Electrocoagulation of Tonsils", Benjamin Ulanski, "A New Conservative Method of Treatment for Tic Douloureux", Frederick D Stubbs, "Phrenic Excision in Treatment of Pulmonary Tuberculosis", and James H Mendel, "Eardrums and Their Interpretation", a display of plaster models showing progressive stages of ear infections and their treatment. Graduate seminars on gynecology were presented, February 14, by Dr George A Ulrich on toxemias and February 21 by Dr Philip F Williams on puerperal sepsis.—Speakers at a meeting of the Philadelphia Pediatric Society, February 11 were Drs Mitchell I Rubin and Milton Rapoport on "Three Major Complications of Acute Nephritis," and Rachel Ash, "Statistical Study of Heart Cases at the Children's Hos-

pital from 1925 to 1935."—Among speakers before the Philadelphia Academy of Surgery, February 12, were Drs Thomas A Shallow, on "Resume of 500 Cases of Osteomyelitis," and Alexander Randall and Frederick A Bothe, "Value of Pre operative Irradiation in Tumor Testis."

Pittsburgh

County Society Offers Courses—The Allegheny County Medical Society has announced the tenth series of practical courses to begin the middle of March and run from four to six weeks each. The subjects will be neurology, recent advances in applied therapeutics, office gynecology, treatment of leg ulcers and the injection treatment of varicose veins, acute communicable diseases, common skin diseases and malignant conditions of the mucous membrane, practical obstetrics, anesthesia and gastro enterology.

Society News—Dr Charles C Higgins, Cleveland, addressed the Pittsburgh Urological Association, February 10, on "Further Experimental Observations on the Production and Solution of Urinary Calculi."—At a meeting of the Pittsburgh Ophthalmological Society, February 10, Dr William L Benedict, Rochester, Minn, read a paper on "Surgical Affections of the Orbit."—The annual R W Stewart Memorial Lecture of the Pittsburgh Academy of Medicine was given by Dr Fred W Rankin, Lexington, Ky, February 11, on "Evolution of Surgery of the Large Bowel and Rectum."

SOUTH CAROLINA

Bill Introduced—S 1176 proposes to repeal those provisions of the dental practice act requiring the annual registration of licentiates.

TEXAS

Dallas Clinical Conference—The eighth annual spring conference of the Dallas Southern Clinical Society will be presented at the Baker Hotel, March 16-19. The program includes general assemblies each morning and graduate lectures, round table luncheon conferences, clinics each afternoon, special conferences Tuesday and Thursday afternoons, a public meeting Monday evening, symposiums Tuesday and Wednesday evenings and a banquet for the final high light of the meeting. The following guest speakers will appear at the general assemblies and take part in other parts of the program:

Dr Edgar G Ballenger Atlanta Disorders of the Posterior Urethra
Dr Hans Barkan San Francisco Injuries to the Eye
Dr Francis G Blake New Haven Conn Treatment of Lobular Pneumonia
Dr Alan G Brown Toronto Meeting the Nutritional Requirements of Infancy and Childhood
Dr Louis A Bue Rochester Minn Diagnostic and Therapeutic Methods in Anorectal Diseases
Dr William R Cubbins Chicago Traumatic Injuries to the Knee Joint
Dr C Frederic Fluhmann San Francisco Sex Hormones and Menstruation
Dr Verne C Hunt Los Angeles Diagnosis of Breast Tumors
Dr Foster Kennedy New York Allergic Manifestations in the Nervous System
Dr Byrl R Kirklin Rochester Minn Diagnosis of Early Pulmonary Tuberculosis
Dr John A Kolmer Philadelphia Susceptibility Immunity and Vaccination in Infantile Paralysis
Dr Walter A Wells Washington D C Hoarseness from the Standpoint of the Otolaryngologist

At the public meeting Dr Kennedy will speak on "Education of Children for Emotional Control" and Dr Kolmer on "Vaccination Against Disease." In a symposium on diseases of the paranasal sinuses speakers will be Drs Barkan, Wells and Kolmer, in one on pelvic diseases, Drs Fluhmann and Kennedy, and in one on acute pulmonary diseases, Drs Blake Brown and Kirklin.

VIRGINIA

University News—Dr Sydney W Britton, professor of physiology, University of Virginia Department of Medicine, University, has received a grant of \$15,000 from the Rockefeller Foundation to finance a three year program of research on the adrenal glands.

Bill Introduced—H 275 proposes to prohibit the distribution, except by a licensed physician or by a licentiate under the pharmacy practice act of articles, devices, drugs or medical preparations manufactured primarily for or which may be used as, contraceptives or for the prevention of venereal diseases or infections.

Personal—Dr Will R Williams Richlands was appointed to the state board of health recently to succeed the late Dr Joseph A McGuire, Norton.—Dr Linwood Farley has been made health officer of Hanover County with headquarters at Ashland.—Dr Quintus H Barney has been elected health officer of Altavista and community succeeding the late Dr John Arnold Board. Dr John W Bowdoin Bloom was recently appointed superintendent of public welfare for Accomac County.

WASHINGTON

Dinner to Dr Clancy—Friends and associates of Dr Frank J. Clancy, Seattle, gave him a farewell dinner at the Rainier Club, January 27. Dr Clancy, who has been executive chairman of the Public Health League of Washington, has been appointed director of the Bureau of Investigation of the American Medical Association, Chicago. Speakers included Drs Nathan L. Thompson, Everett Casper W. Sharples, Otis F. Lamson, Raymond L. Zech, Harrison, Garner Wright, Robert D. Forbes and George W. Swift.

Society News—Drs Bernard D. Harrington and Charles D. Hunter, Tacoma, addressed the Pierce County Medical Society, Tacoma, in December, on bone tumors and on dislocation of cervical vertebrae—Dr Richard B. Dillehunt, Portland, Ore., addressed the Walla Walla Valley Medical Society, Walla Walla, December 12, on pain in the lower back and sacro-iliac discomfort—The King County Medical Society was addressed February 17 in Seattle by Drs Martin Norgore on "Neuroma of the Appendix" and Charles F. Watts, "Coarctation of the Aorta." Dr Roscoe E. Mosiman conducted a pathologic demonstration, all are from Seattle.

WEST VIRGINIA

Personal—Harry K. Gidley, formerly connected with the Kellogg Foundation of Michigan, has been placed in charge of the state WPA rural sanitation program, succeeding Dr Frederick T. Foard, who was recently transferred by the U. S. Public Health Service to San Francisco, where he is regional consultant for the service in a territory embracing nine states, the *News Letter* of the state health department reports.

GENERAL

American Academy Offers Prize—In compliance with the requirements of a gift under the will of the late Francis Amory, Beverly, Mass., the American Academy of Arts and Sciences announces the offer of a septennial prize to be known as the Francis Amory Septennial Prize. The gift provides a fund, the income of which may be awarded for conspicuously meritorious contributions to the field of knowledge "during the said septennial period next preceding any award thereof, through experiment, study or otherwise in the diseases of the human sexual generative organs in general." The prize may be awarded to any person or persons for work of "extraordinary or exceptional merit" in this field. In case there is work of a quality to warrant it, the first award will be made in 1940. The total amount of the award will exceed \$10,000 and may be given in one or more awards. It rests solely within the discretion of the academy whether an award shall be made at the end of any given seven year period and also whether it shall be awarded to more than one person. While there will be no formal nominations, and no formal essays or treatises will be required, the committee invites suggestions, which should be made to the Amory Fund Committee, care of the American Academy of Arts and Sciences, 28 Newbury Street, Boston.

Influenza Virus Desired for Study—The International Health Division of the Rockefeller Foundation wishes to obtain strains of virus from different outbreaks of influenza in order to compare their immunologic characteristics in a study now in progress. Health authorities are urged to notify Dr. Johannes H. Bauer, Rockefeller Institute, York Avenue and Sixty-Sixth Street, New York, by collect telegram or fast mail of any epidemic of influenza, giving any particulars, such as the number of cases and clinical characteristics, that may be available. In an extensive outbreak it may be found advisable to send one of the division's investigators, but in smaller outbreaks the cooperation of the local health authorities is requested. On receipt of notice of an outbreak, containers already sterilized will be furnished with detailed instructions for the collection and shipment of the material. Blank forms for recording information will also be furnished. The material most desired is sputum and nasal mucus throat washings obtained by having the patient gargle either with a bacteriologic broth or with ordinary physiologic solution of sodium chloride, and pieces of lung or bronchial mucus in case necropsy material is available. Also blood specimens taken from some of the patients during the early stage of attack as well as during convalescence will be appreciated. The study on influenza was carried on by the Rockefeller Institute at its hospital until January 1 when it was taken over by the International Health Division to be continued in the division's laboratories at the institute.

American College of Physicians—The twentieth annual session of the American College of Physicians will be held at the Book-Cadillac Hotel, Detroit March 2-6. The mornings will be given over to clinics at various local hospitals and the

afternoons to the presentation of papers. Wednesday has been designated "Ann Arbor Day," with the staff of the department of medicine of the University of Michigan presenting the program. Clinics will be conducted in the morning. In the afternoon, papers will be read by the following:

Alexander G. Ruthven, LL.D. president of the University of Michigan
Address of Welcome
Dr. Fred J. Hodges, Ann Arbor. The Medical and Economic Advantages of an X-Ray Chest Survey of All Hospital Admissions
Dr. Frederick A. Collier, Ann Arbor. Clinical Aspects of Water Balance and Dehydration
Dr. Carl D. Camp, Ann Arbor. Relation Between Emotion and Disturbance of Physiologic Function
Dr. Cyrus C. Sturgis, Ann Arbor. Present Status of Pernicious Anemia. Experience with 600 Cases Over Eight Years
Dr. Max M. Peet, Ann Arbor. Surgical Treatment of Hypertension

The annual convocation will be held at the Book-Cadillac Hotel in Detroit Wednesday evening, when the John Phillips Memorial Medal will be presented. Dr. Walter B. Cannon, George Higginson professor of physiology, Harvard Medical School, Boston, will deliver the convocational oration on "The Role of Emotion in Disease," and Dr. James Alexander Miller, New York, the presidential address, entitled "The Changing Order in Medicine." The annual smoker will be held Monday evening. At the annual banquet Thursday evening, Dr. Henry R. Carstens, Detroit, will be the toastmaster and the speaker will be Jesse S. Reeves, Ph.D., W. W. Cook professor of American Institutions and chairman of the department of political science, University of Michigan. His address will be entitled "New Paths and Old Landmarks."

Medical Bills in Congress—Change in Status H. R. 11035, making appropriations for the military and nonmilitary activities of the War Department for the fiscal year ending June 30, 1937, has passed the House. The bill proposes an appropriation of \$20,660 for the Library of the Surgeon General's Office to purchase books of reference, periodicals and technical supplies and equipment. For the preceding fiscal year the appropriation for similar purposes was \$15,700. The bill proposes no specific appropriation for printing the "Index Catalogue of the Army Medical Library." For the preceding fiscal year, the appropriation for this purpose was \$37,000. The pending bill provides that none of the funds appropriated therein shall be available for any expense on account of any student in the air corps, medical corps, dental corps or veterinary units not a member of such units on May 5, 1932. **Bills Introduced** S. 3984, introduced by Senator Byrnes, South Carolina, proposes to reenact all public laws in effect on March 19, 1933 granting pensions (1) to former members of the military and naval service for injury or disease incurred or aggravated in the line of duty in the military or naval service, other than war-time service, or (2) in the case of death from such injury or disease, to the widows and dependents of such members. S. 4000, introduced (by request) by Senator Copeland, New York, proposes to amend existing laws relating to the dissemination of information concerning the prevention of conception so as to make them inapplicable when such information, or when any article designed, adapted or intended solely for the prevention of conception, is sent, carried or conveyed (1) to any legally licensed practicing physician for the treatment of patients, (2) to any licensed druggist for the sole purpose of filling prescriptions of any such physician, (3) to any legally chartered medical college for medical instruction at such college, or (4) to any legally licensed or chartered hospital or clinic, for the treatment of patients in such hospital or clinic. H. R. 11141, introduced (by request) by Representative Rankin, Mississippi, proposes that, notwithstanding any provision of law to the contrary, in no event shall Veterans' Administration facilities be used, on or after the date of enactment of the bill, to furnish medical and hospital care to persons not eligible to such care under the provisions of the laws providing relief for veterans. H. R. 11142, introduced (by request) by Representative Rankin, Mississippi, proposes to direct the Administrator of Veterans' Affairs to furnish to men discharged from the Army, Navy, Marine Corps or Coast Guard who are suffering from service-connected disabilities, who reside in foreign countries but are citizens of the United States, medical and hospital treatment for such diseases or injuries.

CORRECTION

Tests Used in Studying Hypertensive Disease—In *Queries and Minor Notes* in THE JOURNAL, February 8, page 484, the standard formula employed in determining the blood urea clearance should have read

Standard Blood Urea Clearance = $\frac{U}{B} \sqrt{T}$
instead of with the 666 as printed

Reforms in the School Medical Service

The board of education has issued to the local education authorities a circular indicating reforms of which a large proportion concern the school medical service. The local authorities are told that it is their duty not only to provide for the medical inspection of school children but also to make adequate arrangements for their health and physical condition. They should survey the needs of their areas and consider what further steps should be taken to remedy any deficiencies. The following criticisms are made:

THE SCHOOL DENTAL SERVICE

The school dental service is seriously incomplete in most parts of the country. Authorities should aim at an initial dental inspection of every child on its entry into school, to be followed by an annual re-examination. On this basis the board estimates that a minimum standard for a normal number of acceptances for treatment should consist of one dentist for every 5,000 children in an urban area and for every 4,000 in a rural area, although this is insufficient when a high proportion of parents accept treatment for their children.

ORTHOPEDIC TREATMENT

There should be in every area a scheme designed in conjunction with an orthopedic hospital, to provide for the diagnosis, treatment and after-care of crippled children. Areas which have a scheme should consider the adequacy of the provision of places in orthopedic hospital schools for children who require long periods of treatment.

EAR DISEASES

In view of the need for expert treatment of ear diseases which may result in deafness, authorities which have not yet done so should arrange for the services of part time aural specialists who would visit the areas periodically and advise as to treatment. The work of the specialists should be closely coordinated with that of the aural surgeons employed at the isolation hospitals, since many ear defects in children are due to acute infectious diseases.

OPEN AIR SCHOOLS

In many industrial districts open air schools do not exist or their number is inadequate. The board would welcome an increase in their number. While day schools suffice for most children, there are some who on account of their debilitated condition or exceptional home circumstances, require the more continuous care that can be given only in a residential school. Where sufficient accommodation is not available, the existing voluntary agencies should be considered, and if these prove insufficient, the necessary residential schools should be established.

INSTITUTIONAL TREATMENT FOR ACUTE RHEUMATISM

Increased provision is needed for special institutional treatment of children suffering from or convalescent from acute rheumatism, because of the danger of heart disease. Though the number of cases is small the problem is important. The method of cooperation with local voluntary agencies just mentioned might be followed.

SUBNORMAL CHILDREN

The subnormal child calls for careful attention. While additional day special schools for mentally defective children are not as a rule, urgently required there is need for increased

residential provision for difficult children or those of low grade intelligence who are out of reach of or unsuitable for day special schools but cannot properly be retained in the ordinary public elementary school.

THE BLIND AND DEAF

The accommodation for blind and deaf children in the country is generally sufficient, but some additional provision for partially sighted and partially deaf children is desirable.

PHYSICAL EDUCATION

The board states that health can be maintained and improved only by systematic physical education. While organized games play an important part in this, the best means of securing continued physical fitness is by physical exercises in school premises or in the open air. Local authorities should frame comprehensive schemes of physical education. The board proposes to issue a circular dealing with the whole question including the provision of physical education for young people who have left school. A centralized system of the continental type would not be appropriate, but organized local development is essential.

Voluntary Euthanasia

As previously stated the proposal to legalize voluntary euthanasia has met with a good deal of criticism from the medical profession. A discussion took place at a meeting of the West Norfolk division of the British Medical Association in which the legal profession also was represented. Dr P. S. Marshall said that the bill tended to deprive the patient of hope, which was of vital importance in the worst cases. It introduced a disturbing element in the household of the patient and might lead to recriminations in the family afterward. The whole procedure would add much to the patient's distress and the physician's difficulties. From his experience he thought that only exceptionally few cases would come within the scope of the bill, while many patients who were a burden both to themselves and to the community were left out.

Mr Coulton a lawyer, said that the proposals cut right across the long established law of England and that public opinion was still much against suicide. As always there was a time lag between the proposed reform and the education of public opinion. There should be certain safeguards, the physician should not in any way benefit from the death of the patient and should be immune from subsequent action by the relatives.

In the discussion the majority of the speakers were against the proposal chiefly on the ground that there was no call for it and because it excluded many people of the type mentioned by Dr Marshall. On the legal side it was suggested that in nearly all cases of suicide the individual was insane and therefore no man in his senses would sign a document that he wished to take his life. But on the medical side this was not accepted, and it was averred that coroners' verdicts of 'suicide while temporarily insane' were by no means strictly scientific.

Dr C. K. Millard, honorary secretary of the Voluntary Euthanasia Legalization Society, dealt with the objections raised. The number of cases that might come under the bill was a matter of opinion but this should not be a bar to its going forward. The measure was humane. No vote was taken on the bill.

Indian Women and Birth Control

The All-India women's conference at Trivandrum has passed a resolution affirming that there is need for instruction in birth control through recognized clinics and calling on the constituencies to make special efforts to induce municipalities and other organizations interested to open centers to give such instruction to all needing it. The resolution was carried by 80 votes to 25. Though it repeats the one of last year it is passing in Travancore where birth control has many opponents is regarded as significant.

Tuberculous Nurses

Tuberculosis is especially fatal to young women and frequently attacks nurses. The directors of the Papworth Village Settlement for Tuberculosis, the pioneer institution of this kind, which has been copied all over the world, have produced a scheme for dealing with the problem. In a letter appealing for funds, published in the *Times*, they point out that after sanatorium treatment the tuberculous nurse is faced, like other sufferers with the necessity of earning her living, but with the difference that her profession often leads her into sick-rooms. If she confesses that she is tuberculous, she destroys her chance of employment. If she conceals the fact, she may come into contact with persons whose lowered resistance makes them susceptible to infection. Recognizing this and conscious of the menace to public health, Papworth has decided to offer a third choice, of great value to these unfortunate nurses and to the community. It proposes to build a special home for tuberculous nurses who come there for treatment and, when active treatment is concluded, to employ them in the exercise of their profession or in other suitable employment under the special conditions which their health requires. These nurses will thus be rendered as nearly as possible self supporting and the community will be protected against infection. At present applications for employment are frequently made to Papworth by tuberculous nurses some of whom have received sanatorium treatment but cannot afterward obtain suitable employment.

The Lack of Sanitation in France

In the *Concours medical* Dr J. Noir emphasizes the slacking of their duty by the authorities in the matter of sanitation, public hygiene and simple cleanliness. For more than fifty years public education has been compulsory in France and hygiene is given a prominent place in every school. But the people remain about as ignorant in hygiene and sanitation as in past centuries. An example would have to be given by the administrations, which in France are under government control. Consider the buildings in the prefecture of the Seine or in any bureau in France. They sometimes are dilapidated and too often nobody worries about cleanliness, the result is awful. In a lot of government buildings, for instance the duty of cleaning the windows is entrusted to two different departments, the outside to some ministry, the inside to the local authority. The result is that when one side is clean the other is dirty.

The ministry of public health, about which the hygienists indulged in beautiful dreams, is a portfolio to be given to some politician who will be superseded by another one equally inadequate when he begins to learn something about his job. Only one of the ministers of public health has been a physician or some other competent person since the creation of this ministry.

Dr. Georges Schreiber in the bulletin of the Parti social de la sante publique points out that the public health law of 1902 is without virtue because the mayors who are in charge of it do not worry about it. In Paris where the police should take more pains to enforcing the law nobody cares the simpler regulations, such as forbidding the exposure of eatable goods to dust and the obligation to wrap bread and fruit, are neglected. The food may be pawed over by anybody and the flies may help themselves first anybody may spit on the ground. The police never arrest any one or if they do the intervention of some alderman releases the offender.

Some departments directly under the control of authorities and managed by technicians are better for instance the inspection of meat or milk in the slaughterhouses or dairies. In some cases, private initiative has succeeded in bettering the

conditions of a whole sanitary department, the Touring Club for instance exerts good control over the country hotels and the automobile associations have made tolerable the policing of the roads. But, on the whole one can hardly hope for a great advance in general sanitation in France except by the education of the public, which is a long and hard task.

The Prevention of Hereditary Syphilis

In the *Concours medical* Professor Gougerot defines the general rules of the prevention of hereditary syphilis. This disease is in France more than a disease it is a national peril and France cannot afford to lose human capital, by death, unfitness or lunacy, conditions that are the future of the syphilitic stock. According to Professor Gougerot, the first step is to avoid procreation before complete recovery from syphilis.

The recognized conditions of a cure, in France are as follows:

A period of two or three years after the chancre, if the treatment is begun early, and four or five years if treatment is initiated a fortnight after the chancre. Regular treatment during this period, with compounds of arsenic, bismuth and mercury.

Absence of any lesion during at least two years.

Normal character of the disease, i.e., exclusion of the arsenic resistant or bismuth by resistant cases.

Negative blood test made by the most sensitive methods, such as the Harrison-Wyler or Sorelli-Miravent, or the flocculation method, Kahn's type.

Negative spinal fluid test.

Another means of security, the second one is to have the two apparently cured prospective parents treated for two or three months before the wedding.

A third means is to treat always the future mother during her pregnancy. But here the opinions differ. Some physicians advise treatment in every case, even if the preventive standards have been satisfied. Professor Gougerot limits the treatment of formerly syphilitic and actually pregnant women to the cases in which clinical or serologic activity is present in one of the parents or both or in whom the blood test was positive less than two years before when the previous pregnancies were unsuccessful when some of the first children were deficient or unsound, and when the parents show some transmissible taints.

The Blood Sugar in Hypertension

In the *Progres medical* Drs. G. Carriere and Claude Huriez discuss dextrose metabolism in hypertension. They studied 105 cases in which there was a permanent high blood pressure above 200. The blood sugar in fasting showed a slight increase in ninety-four cases of hypertension and a decrease in eight cases. As to the frequency of permanent high blood pressure in diabetes the authors think that it could be figured between 14 and 30 per cent but it never occurs in juvenile diabetes. The older a diabetic patient is the more he is liable to get hypertension as a result of arteriosclerosis.

The Treatment of Scoliosis

The ankylosing graft operation seems to have been initiated by Professor Ombredanne who at any rate applied it in forty cases presented before the Societe de pediatrie of Paris. General preparation of the patient, who is often underweight is necessary. Such preparatory nursing reduces the mortality from intervention. As for the operation one can use different techniques the Albee operation which is often impossible because of the curve of the vertebrae the Hibbs operation, which is long and complex the Halstead operation and Professor Ombredanne's technique which consists in taking a graft from the tibia. The graft is kept sterile and the tibial section is closed. The patient lies on the bed, flat on the face. The bone graft is inserted between the posterior and the anterior part of the vertebral processes. The main complication is shock which killed three of Professor Ombredanne's patients (two more are dead of septicemia). One can reduce the incidence of the

shock with preoperative care and by performing the operation in two or three stages. The skill of the surgeon is of great moment in shortening the duration of the operation. The results are satisfying. While the graft maintains well enough the rigidity, in four cases the deformity was aggravated.

Bercovitz's Method for Early Diagnosis of Pregnancy

Bercovitz in 1930 proposed a simple method for the early diagnosis of pregnancy, consisting of dropping in the corner of one of the patient's eyes a few drops of her own serum or of her own blood with an admixture of sodium citrate. Two minutes later, according to the time of day, the amount of illumination and the former condition of the pupil, a partial myosis or mydriasis of the treated eye appears, which is easily ascertainable by comparing with the other eye. This reaction was averred to be positive in 84.7 per cent of the cases observed. In the Société d'obstétrique et de gynécologie of Paris, Dr. L. Pouliot introduced some minor changes in Bercovitz's technique. He found it convenient to look first at both eyes with a mild illumination and then suddenly to throw a bright light on the eyes. Pouliot tried the Bercovitz test on forty-four women. Every woman with a positive test was found to be pregnant. In two cases the early diagnosis was important because of an extra uterine pregnancy. These diagnoses were all made before any clinical evidence of pregnancy, or even any suspicion, for instance after only eight days of delay of the menses. Pouliot concludes that: 1. A clear-cut positive reaction certainly indicates pregnancy. 2. One must consider as positive only myosis of the treated eye, pupillary changes leave room for doubt. 3. Negative reactions, without any clinical symptom of pregnancy, have very slight value, at least till the suppression of a second menstrual period. If the test is negative, and the pregnancy on the other hand is clinically probable, one must allow for the possibility of a retained dead ovum.

Dec. 26, 1935

Bureau to Combat Violation of Antinarcotic Laws

For the purpose of waging a more efficient struggle against the illicit traffic in narcotics, the ministry of the interior has established, with immediately gratifying results, a government central headquarters for combating offenses against the antinarcotic laws. This bureau functions in conjunction with the previously existing antinarcotic activities of the Prussian crime detection bureau in Berlin. At the same time branches of the central bureau have been set up throughout Germany. Local authorities must report to these coordinating bureaus all cases of more than a local significance. This must be done immediately if there is reason to suspect a criminal trade the ramifications of which are more than local and which is engaged in by professional criminals.

Suspects are also reported whose extensive journeying or foreign contacts might connect them with the sale and procurement of narcotics. Furthermore, pharmacy burglars, recidivist thieves and swindlers are reported to the bureau. As for drug addicts whose defective responsibility exempts them from criminal prosecution their commitment to a hospital is effected. All cases involving administration of health regulations are reported to the ministry of health, the cooperation of which is assured. Furthermore, the government central bureau is provided with a card index of known criminals.

Crime-Commissioner Thomas, writing on the narcotic question in the *Zeitschrift für Polizeiwissenschaft* states that the number of drug addicts is difficult to determine but that the proportion is scarcely greater than one to each 10,000 inhabitants. When however the number was last computed in Germany (1928) there were estimated to be between 6,000 and 8,000 chronic

opium addicts in the country. Meanwhile the still incomplete card index of the central bureau lists more than 1,000 who have been held subject to criminal prosecution. These figures show cause enough why the antinarcotic campaign should receive the vigorous attention of the authorities. While in the past it was customary for addicts considered mentally irresponsible to be released as immune from prosecution, the National Socialist government has taken measures to protect the general public against law breakers of this type. It is now possible in case of manifest irresponsibility to commit the offender for an indefinite period of time to an institution wherein he will receive proper treatment.

Group Examinations for Cancer

The Königsberg gynecologist Professor von Mikulicz-Radecki points out in *Der öffentliche Gesundheitsdienst* that according to careful estimates cancer is present in about a quarter of a million people in Germany (about one in every 240) and of these one fourth are under the age of 40. A majority of those afflicted with cancer still succumb to this disease. An organized anti-cancer campaign must be based on early diagnosis and must have as its aim the detection of the cancerous condition at such an early stage that favorable prognosis may be indicated in 80 per cent of the cases. Every citizen ought to be acquainted with the nature of cancer, and every physician should be in a position to recognize cancer in its earliest manifestations. A most efficient measure in the fight against cancer may be the systematic group examination of all healthy persons who have arrived at an age when a greater danger of cancer exists. In East Prussia, the capital of which province is Königsberg, this idea was attempted in 1933. No striking success was realized at that time, however, as the women would not come voluntarily for examination. Thereupon the bureau of people's health of the National Socialist party in cooperation with the East Prussian administrative board inaugurated a large scale anti-cancer offensive. In 1936, group examinations will be undertaken not only in all the hospitals in the city of Königsberg but throughout the province as well. The examinations have already disclosed a whole series of cancerous conditions of which the persons themselves had no presentiment and which involved the mammary glands as well as the genitals. In the meantime the activity of the examining clinics had been discussed among the population with the result that the women now began to come voluntarily to be examined. This goes to show that cancer fear need not be produced by such measures as these.

Regulation of Blood Stream Resistance in the Lungs

The Breslau physiologist Professor Wagner recently pointed out the important factors that influence the pulmonary circulation, such as resistance changes in the pulmonary capillaries, transmission of the intrathoracic pressure, and changes in the beat volume due to changes in the blood supply. Of especial importance is the alteration in the course of ventricular pressure during inflation of the lung and its relation to the expulsion period of the right ventricle. From prolonged inflation the values of the maximum systolic pressure in the right ventricle are finally decreased because the amount of blood supplying the right ventricle must decrease below its outgoing volume. It is thus shown that the position of the thorax is of importance for the function of the right ventricle. If, during inflation, the thorax finds itself for some time nearer the expiratory position, the right ventricle is able to shut off the blood through the lungs with less exertion than if the thorax were near an inspiratory position. Considering the action of the reserve capillaries, it is to be expected that an increased pulmonary inflation would lead to a greater blood perfusion of reserve capillaries so that with an increased inflation the blood stream in the lungs is spread over a greater surface. Since only the surface of the blood stream comes into consideration as a gas exchange surface apparently it may be possible for the organism to control the

respiratorily active blood surface according to the degree of pulmonary inflation. The reflex apparatus, first described in its effect by W. R. Hess of Zurich, which provides for a tonic adjustment of the respiratory musculature, particularly the diaphragm, is important in the adaptation of the respiratorily active surface of the blood stream within the lungs. This apparatus, which gives the respiratory muscles tonicity, apparently effects a correlation between minute volume in the pulmonary circulation and respiratory exchange of gases. The tonic component, which is determined by the extent of the deepest expiratory position, probably serves chiefly the adjustment of the active respiratory surfaces of the blood stream, whereas the respiratory movements chiefly supply the air exchange for the tonicized fixed respiratorily active blood surface and, as it were, breathe on it. The respiratory movement takes place in such a way that at no time will there be a reduction of the tonicized fixed minimal surface of the blood stream, which is determined by the expiratory position. One concludes that the respiratory center has a double purpose. Its rhythmic fluctuations of irritability serve the air exchange, while its tonic control probably serves principally the regulation of the respiratorily active surfaces of the blood stream within the lungs.

Group Roentgen Examinations in Combating Tuberculosis

Group roentgen examinations for the determination of tuberculosis have been undertaken for some time now. Particularly in Switzerland have noteworthy results been reported. Recently Dr. Misgeld made a report to the Berlin Medical Association on experimentation in this field. When one realizes that today the number of actively tuberculous persons in Germany amounts to from 300,000 to 400,000, together with a million threatened with the disease, one can scarcely overestimate the importance of a defensive campaign against this plague. Roentgenologic control is in particular requisite to the arrest of latent tuberculosis. How often potentially infectious tuberculosis can run a course nearly free from subjective symptoms is demonstrated by the result of a group roentgen examination of some 850 men, members of a special formation unit of the Schutzstaffel of the National Socialist party. Again and again cases of active tuberculosis were discovered. It is therefore indicated that compulsory roentgen examinations should be instituted at least wherever people are brought together in great communities.

ITALY

(From Our Regular Correspondent)

Dec. 22, 1935

The Annual Congress of Internal Medicine

The forty-first National Congress of Internal Medicine was held this year at Bologna (the meeting place of all medical congresses) with Senator Prof. Giacinto Viola presiding. In the opening address the esteemed Senator Prof. Edoardo Maragliano pointed out that the method followed by the society for the last half century is that of collective critical evaluation. Up to the present, 120 different topics have been dealt with in this manner. The dominant principle is the study of the patient. All clinics are biologic but concerned solely with that part of biology which is applicable to the understanding of the patient. Many clinical schools of Italy cooperate with the main school in keeping the society active and alive and for some years now the medical corps of the army has participated in the work of the society. He stated that, as the result of collaboration with the society of surgery, several specialties have been developed, such as hematology and legal medicine two recently added. But internal medicine and surgery must remain the directing and unifying centers of all the specialties. After analysis comes synthesis increasingly important at present in view of recent discoveries which show pathologic conditions as resulting not from the disease of a single organ but from anatomic and functional correlations between various organs.

The first subject, "Evaluation of the Individual Constitution," was divided into four parts: (1) "The Present Situation of the Scientific Movement with Regard to Individual Constitutions," by Dr. Benedetti, (2) "My Method of Evaluation of the Individual Constitution," by Dr. Viola, (3) "Growth from Ages of 11 to 17 and the Measurements That Assist in the Evaluation of the Individual Constitution According to the Viola Method," by Dr. Schiassi, (4) "The Psychologic Evaluation of the Individual Constitution," by Dr. Capone.

Dr. Benedetti stated that, differing in this respect from others, the Italian school understands by individual constitution the total of all the characteristics, somatic, functional, organic and psychologic, that differentiate one person from another. This school considers the sole object of its research to be the evaluation of the person in his complexity (phenotype), as a variant from the anatomic functional level of the species, modified by environment and the laws of heredity. The study of the person is arrived at only by means of lengthy approach in which figure the anatomy, physiology and pathology of the average type of our species, thus many factors are involved, such as the constitution according to race, ethnic group, sex, age and social station. The speaker reviewed recent foreign and Italian scientific contributions to the argument, making clear the differences between the foreign schools and the Italian school, which is based on the thought of De Giovanni, Viola, Castellino and Pende. The science of the individual constitution is new and as such leaves much to be accomplished.

Dr. Viola stated that, since the constitutional variability of characteristics is quantitative, the only method of research applicable to constitutional science is anthropometry, whether external or internal, functional, organic or psychologic. Anthropometric research is not limited to the measurement of the individual variants of each character but takes into account their evaluation according to the norm of individual statistics. The individual variations of characteristics and their combinations are infinite, but all are subject to the law of accidental errors of Quetelet, which finds its graphic expression in the curve of Gauss, characteristically bell-like in form. Viola's objective method of evaluation gives a double conception of the evaluation of each human characteristic in centesimal and sigmatic degrees and has for its unique object of study the average man considered as a systematic unit derived from a synthesis of normal values of all the characteristics considered. The existence of this average man, demonstrated by Viola during the last thirty years, is confirmed by new observations. Viola's external anthropometric method is based on ten simple fundamental measurements (closed system) from which are obtained, by simple calculations, a series of relationships that become gradually more complex as their elaboration proceeds. The second phase of Viola's method is concerned with the evaluation of functional individuality, which is based on the direct quantitative determination of a number of organic functions, on the study of interfunctional relationships and on the elaboration of certain synthetic indexes, which become gradually more complex until the formation of the general index of organic power. The important synthetic indexes have to do with the perimetral average of the limbs, the dynamometric average, the cardiac value and the indexes of cardiac power. A series of relationships (spiro-somatic, spiro-thoracic, spiro-cardiac) are drawn from these indexes. From these first synthetic evaluations he goes to more comprehensive evaluations represented by the static index and the dynamic index of organic power, whence he derives as a synthesis of the third order the general index of organic power. In such a way the individual is evaluated on the basis of a uniform system, founded on mathematics, which resolves the problems that beset the practicing physician when he attempts to characterize people as robust, average or delicate.

Dr Schiassi set forth the results of a study of that period of growth during which sexual maturity takes place. The groups studied consisted of males and females varying in number between fifty and a hundred. The result of many measurements shows that the most intensive development takes place in female subjects aged from 12 to 14 and in male subjects aged from 13 to 15. At the age of 10 the measurements of male subjects are nearly equal to those of female subjects from 12 to 14, the curve of the female subjects runs above that of the males throughout the greater part of linear and cubic measurements. This growth coincides with, or slightly precedes, the definite manifestation of sexual maturity in fact from 20 to 25 per cent of Bolognese girls first menstruate at the age of 13, and 98 per cent of these girls are menstruating at the age of 15.

Dr Capone, in the study of psychologic evaluation of the individual constitution distinguishes a cortical or superior personality and also an instinctive or fundamental personality. He finds that, as the values of the superior personality and of the affective personality are raised, the percental number of long types is increased. The number of extroverts (in the precise sense of Jung) increases. With the rise of the affective personality, the percental number of tachypsychic persons increases.

The second paper on the diagnosis of icterus, was by Senator Prof Ferdinando Micheli of Turin, assisted by Drs Dominici and Allodi. Dr Micheli said that icterus is a symptom rather than a syndrome. When in addition to the yellow color there are such other symptoms as pruritus, bradycardia or hemorrhage these are no longer attributed to certain constituents of bile, as was formerly done. The diagnosis is difficult and sometimes extremely serious. In each case in which the diagnosis of icterus does not appear obvious, one should proceed to classify the icterus as belonging to one of four groups: mechanical, hepatogenous, hemolytic or prehepatic and hepatic-cholangitic. The second phase of the diagnosis consists of subclassification of the individual case into further categories. The ease with which this may be accomplished depends on the thoroughness of the examination.

D Amato illustrated his studies on the chemical changes in bile following hepatic, chemical and bacterial intoxication. He believes that when icterus is not present the changes may be in the hepatic cell; when icterus is present, cellular disturbance and changes in the biliary capillaries are manifest.

For the next congress the following subjects were chosen: (1) cardiac decompensation (Dr Cesa-Bianchi), (2) lipodystrophy and constitutional emacration (Dr Galli) and (3) sellar tumors (in conjunction with the society of surgery).

Marriages

WALTER W BROWN, Willford Ark., to Miss Margaret McLeod of Sault Ste Marie, Mich., recently.

JOHN EDWIN BROWN JR, Columbus, Ohio to Miss Rosamond Lawson Foote of Baltimore, Dec 28, 1935.

WALTER GRADY BISHOP, Greenwood, S C, to Miss Martha Thurmond of Spartanburg in January.

JOHN GORDON BELL, Covington Va., to Miss Anna Lee Paschall of Richmond, Nov 30 1935.

RICHARD LAWRENCE DAY, Ridgewood, N J, to Miss Ida Elizabeth Holt of Summit, January 10.

RODOLPH FOWLKES, Welch, W Va., to Miss Rinda Elizabeth Gay of Chatham, Va., Dec 11, 1935.

GEORGE LOUIS JONES, Ridgeway Va., to Miss Ruth Margaret Wilson of Richmond Dec 14 1935.

ANGUS HINSON, New York to Miss Johnnie Lea Black of Chase City, Va., Oct 19 1935.

BERNARD H BAYER, Houston Texas, to Miss Rebecca Miller of New Orleans recently.

Deaths

Rea Everett Smith of Los Angeles, University of Pennsylvania Department of Medicine, Philadelphia, 1902, member of the American Surgical Association, member and past president of the Pacific Coast Surgical Association, fellow of the American College of Surgeons, clinical professor of surgery, University of Southern California School of Medicine, formerly professor of clinical surgery, College of Medical Evangelists served during the World War, on the staffs of the Los Angeles General Hospital, Good Samaritan Hospital, Methodist Hospital and the Cedars of Lebanon Hospital, aged 59, died suddenly, Nov 29, 1935 of coronary thrombosis while aboard a yacht.

Parran Jarboe, Greensboro, N C, Georgetown University School of Medicine, Washington, D C, 1905, member of the Medical Society of the State of North Carolina, fellow of the American College of Surgeons, formerly secretary of the Guilford County Medical Society, on the staffs of St Leos Hospital, L Richardson Memorial Hospital, Sternberger Childrens Hospital, Wesley Long Hospital and the Glenwood Park Sanitarium aged 53, died Dec 29, 1935, in a hospital at Shelby, of injuries received in an automobile accident.

William Oliver Floyd of Nashville, Tenn., University of Nashville Medical Department, 1910 served during the World War, member of the Southern Surgical Association, fellow of the American College of Surgeons, assistant in clinical surgery, Vanderbilt University School of Medicine since 1925, member of the surgical staffs of the Vanderbilt St Thomas, Nashville General and City hospitals, aged 56, died, January 12, of pneumonia.

Roy Seymour Watson of Saginaw, Mich., Rush Medical College, Chicago 1904 member of the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons, served during the World War, chief of otolaryngology, Saginaw General Hospital, aged 53, died, Nov 27 1935 of chronic myocarditis.

Franklin Elmore Ray, Shelbyville, Ind. Medical College of Indiana Indianapolis, 1890 member of the Indiana State Medical Association, at one time county coroner and member of the county board of health aged 70 on the staff of the Major Memorial Hospital, where he died Dec 18 1935 of septicemia due to an injury to a finger.

Millington Smith of Oklahoma City, Missouri Medical College St Louis, 1881, professor of gynecology, emeritus University of Oklahoma School of Medicine, fellow of the American College of Surgeons, medical director of the Mid Continent Life Insurance Company aged 75 consulting surgeon to University Hospital and St Anthony's, where he died January 9, of carcinomatosis.

James Edward Davis of McAlester, Okla., Hospital College of Medicine, Louisville, Ky 1904 past president of the Pittsburg County Medical Society on the staffs of the Albert Pike Hospital and St Mary's Infirmary, aged 56 died Dec 20 1935 in the A C H Hospital, Shawnee, of injuries received in an automobile accident.

Emil Otto Krueger of Michigan City, Ind. University of Michigan Department of Medicine and Surgery, Ann Arbor 1908 past president of the La Porte County Medical Society on the staffs of the Clinic Hospital and St Anthony's Hospital, aged 50, died, Dec 22, 1935 of abdominal abscess and organic heart disease.

Dennett B Hamilton, Dodgeville Wis. Wisconsin College of Physicians and Surgeons Milwaukee, 1899 member of the State Medical Society of Wisconsin on the staffs of the Dodgeville General Hospital and St Joseph's Hospital, aged 59 died, Dec 20 1935 of intestinal obstruction due to postoperative adhesions.

Francis Xavier Mahoney, Boston Harvard University Medical School, Boston 1905 member of the Massachusetts Medical Society, health commissioner of Boston formerly chairman of the city board of health aged 65 died January 14 in the Deaconess Hospital, of carcinoma of the liver and pancreas.

Hubert Livingstone Miller of Captain U S Army retired Seattle University of Pennsylvania Department of Medicine Philadelphia 1905, served during the World War entered the medical corps of the U S Army in 1920 as a captain and retired in 1923 for disability in line of duty aged 53, died Dec 7 1935.

Edgar F Fincher Sr, Atlanta Ga. Atlanta College of Physicians and Surgeons 1901 member of the Medical Association of Georgia, on the staff of the Piedmont Hospital for

many years member of the board of trustees of the Grady Hospital, aged 66, died, January 7, of coronary sclerosis

William James McCollum, Toronto, Ont., Canada, Victoria University Medical Department, Coburg, 1894, formerly associate in medicine and clinical medicine University of Toronto Faculty of Medicine, for many years on the staff of St Michael's Hospital, aged 63, died, Dec 24, 1935

Daniel Henry Cunningham, Chicago, Jefferson Medical College of Philadelphia, 1893, instructor in medicine, College of Physicians and Surgeons, 1903-1907 on the staff of the Hospital of St Anthony de Padua, 1905-1914, aged 71, died, Dec 28, 1935, of chronic nephritis and hypertension

Dana Elbra Monroe * Cameron, Texas, Johns Hopkins University School of Medicine, Baltimore, 1910, past president and secretary of the Milam County Medical Society, served during the World War, on the staff of the Cameron Hospital, aged 51, died, Nov 25, 1935, of septicemia

Homer Tomlinson Partree * Torrington, Conn., Yale University School of Medicine, New Haven, 1892, formerly medical inspector for the schools and health officer of Eaton-town, N. J., on the staff of the Charlotte Hungerford Hospital, aged 70, died Dec 9, 1935, of pneumonia

Rufus Herbert Carver * Providence R. I., Harvard University Medical School, Boston 1870 on the consulting staff of the Providence Living-In Hospital and on the courtesy staff of the Rhode Island Hospital, aged 86, died Dec 30, 1935 of hypostatic pneumonia

Edwin Harper Linfield, Alexandria La. Tulane University of Louisiana School of Medicine New Orleans 1920 on the staff of the Veterans Administration Facility, aged 39, died, Dec 28, 1935, in Jonesville, of injuries received in an automobile accident

George Earl Low, Grants Pass Ore., Willamette University Medical Department Salem, 1912 served during the World War, aged 50, died Dec 9 1935 in the Veterans Administration Facility, Portland, of carcinoma of the stomach with metastases

Irwin Zepp Kinsey, Souderton Pa. Jefferson Medical College of Philadelphia, 1926, member of the Medical Society of the State of Pennsylvania, on the staff of the Grand View Hospital, Sellersville, aged 46, died Dec 8, 1935 of heart disease

George Francis Sullivan * Hoboken N. J., University of Pennsylvania Department of Medicine, Philadelphia 1907, aged 50 on the staff of St Mary's Hospital, where he died, Dec 23 1935, of coronary thrombosis and arteriosclerosis

William Irvin Messick, Baltimore, University of Maryland School of Medicine, Baltimore, 1895, formerly associate professor of clinical medicine at his alma mater, aged 66, died January 3, in the University Hospital, of diabetes mellitus

Jacob Wells Meighen, Ulen Minn., University of Minnesota Medical School Minneapolis, 1896, formerly on the staff of St Ansgars Hospital, Moorhead, aged 72 died Dec 9 1935 in Minneapolis, of pneumonia and cerebral hemorrhage

Charles Abel Howland, Schenectady, N. Y. Baltimore Medical College, 1908, member of the Massachusetts Medical Society served during the World War, aged 58 died Dec 28 1935, of coronary thrombosis and arteriosclerosis

Thomas Nelson Schnetz, Milwaukee, Rush Medical College Chicago 1884 formerly associate professor of physiology, Milwaukee Medical College, aged 75, died Dec 17 1935 of carcinoma of the prostate and bronchopneumonia

George H. Herring, Slocomb, Ala. Georgia College of Eclectic Medicine and Surgery, Atlanta 1898, member of the Medical Association of the State of Alabama, aged 58 died in December 1935 of pneumonia

Carl Ludwig Knitter Jr., Chincoteague Va. Hahnemann Medical College and Hospital of Philadelphia 1928, aged 35 died Dec 25 1935 at the Johns Hopkins Hospital Baltimore, of pneumonia and brain tumor

Frederick Smith Clark, Columbus Ohio. Ohio Medical University Columbus 1907 member of the Ohio State Medical Association, aged 59 died Dec 9, 1935, in the White Cross Hospital of heart disease

Westley W. Halliburton, Alton Ill. Missouri Medical College St. Louis 1878, member of the Illinois State Medical Society, aged 84 died Dec 28 1935, in St. Joseph's Hospital, of cerebral hemorrhage

William P. Parrish, Chatham Va. Baltimore Medical College, 1891, member of the Medical Society of Virginia formerly mayor of Chatham, aged 69, died Dec 6, 1935 of arteriosclerosis and hypertension

Solomon Crittenden Jones, Buileys Switch, Ky., University of Louisville Medical Department, 1898, member of the Kentucky State Medical Association, aged 66, died Dec 25, 1935, of heart disease

Joseph H. Schnell, Houston Texas, University of Pennsylvania Department of Medicine, Philadelphia, 1872, aged 85, died, Dec 13, 1935, of cerebral hemorrhage, chronic nephritis and arteriosclerosis

Charles Sledge Coker, Crosby, Texas, Dallas Medical College 1904, aged 76 died Dec 19 1935 in the Memorial Hospital, Houston, of hypertensive heart disease, nephritis and bronchopneumonia

Harvey Whiting Humphrey, Lowville N. Y. New York University Medical College, 1897, member of the Medical Society of the State of New York, aged 64 died, Dec 21 1935, of myocarditis

Luther Green Probasco, Whitesville, N. Y., Baltimore Medical College, 1898, member of the Medical Society of the State of New York, aged 63, died, Dec 24, 1935, of chronic myocarditis

Joseph J. Clark, Tishomingo, Okla. University of Louisville (Ky.) Medical Department 1896 formerly member of the state legislature, aged 60, died suddenly Dec 10 1935 of heart disease

Henry B. Pack, Blacksburg Va. College of Physicians and Surgeons, Baltimore 1905 aged 57 died Dec 2 1935, in the New Altamont Hospital Christiansburg of coronary thrombosis

Alfred C. Heritage, Jenkintown Pa. Hahnemann Medical College of Philadelphia, 1884, aged 77, died Dec 11, 1935 at his winter home in St. Petersburg, Fla., of bronchopneumonia

David Cummings McLaren, Ottawa, Ont., Canada McGill University Faculty of Medicine Montreal Que., 1880, Hahnemann Medical College of Philadelphia, 1881 died, Dec 30, 1935

Alfred William Christopherson, Pendleton Ore., University of Oregon Medical School, Portland 1928 member of the Oregon State Medical Society, aged 34, died, Dec 3, 1935

George Francis May, London, England, McGill University Faculty of Medicine, Montreal, Que., Canada, 1895, served during the World War, died suddenly Oct 16, 1935

George B. M. Bower, Fort Wayne, Ind., University of Maryland School of Medicine, Baltimore 1887, aged 73 died Dec 28 1935, of uremia and prostatic obstruction

John Fletcher Massey * Ventnor, N. J. Tennessee Medical College, Knoxville, 1903, served during the World War, aged 63 died Dec 21 1935 of angina pectoris

William Compton Harris, Houston, Texas, St. Louis College of Physicians and Surgeons 1891 aged 65, died Dec 13 1935, of chronic myocarditis and hypertension

George White, Chicago, Kentucky School of Medicine Louisville, 1881, aged 80, died, Dec 17, 1935, in the Roseland Community Hospital, of cerebral hemorrhage

L. K. Swango, Carlisle, Ky. Louisville Medical College 1891 member of the Kentucky State Medical Association, aged 68 died, Dec 12, 1935, of heart disease

Thomas Warren Knight, Portage, Ohio Hahnemann Medical College and Hospital, Chicago 1893, aged 80 died Dec 4 1935, of hypostatic pneumonia

Lewis Scott Harvey, Council Grove Kan. University Medical College of Kansas City Mo. 1901 aged 56 died Dec 16, 1935, of cerebral hemorrhage

John K. Knorr, Ventnor, N. J., Jefferson Medical College of Philadelphia 1867 aged 89 died Dec 25 1935 of chronic myocarditis and arteriosclerosis

Elbert Ernest Cone, Oxford Neb. Eclectic Medical Institute, Cincinnati, 1892, aged 69, died, Dec 31, 1935, of myocarditis and bronchopneumonia

Edward E. G. Weiland, Bloomington Ill. (licensed in Illinois in 1895), aged 67 died, Dec 14 1935 as the result of injuries received in a fall

Alonzo Richard Hodge, Severn N. C., Medical College of Virginia, Richmond, 1925, aged 35, died, Dec 12, 1935 of pneumonia and influenza

Joseph H. Miller, Fremont, Neb., Omaha Medical College, 1888, aged 75 died Dec 11, 1935, in the Clarkson Hospital, Omaha of peritonitis

John Joseph McLaughlin, Chicago Long Island College Hospital Brooklyn 1879, aged 77, died, Dec 30, 1935, of myocarditis

"USE OF UNSATURATED FATTY ACIDS IN TREATMENT OF ECZEMA"

To the Editor—In *THE JOURNAL*, January 4, page 64, Dr J F McClendon replied to our article on "The Use of Unsaturated Fatty Acids in the Treatment of Eczema" (*THE JOURNAL*, Nov 23, 1935, p 1675), citing his own experience with vegetable oils in the diet. He also calls attention to the deleterious effects of the lack of vegetable oils in the diet of the Japanese. Vegetable oils have been used from time immemorial by all races as a food.

However, the aim of our paper was to decry the promiscuous use of linseed oil as a therapeutic agent in atopic conditions.

Recently our attention was called to another article on hypersensitivity to linseed oil by Dr Charles Sutherland (*M J Australia* 2 661 [Nov 15] 1930). Two patients who were asthmatic had severe attacks of asthma after the use of linseed oil. Linseed oil and cottonseed oil contain active rotopen and may produce symptoms by inhalation, ingestion or as a contactant, in atopic individuals. Coca emphasizes this fact, particularly with reference to cottonseed oil, in his book on asthma.

COLON IRRIGATIONS

To the Editor—If there is no agreement regarding a therapeutic measure that has been in use for a long time its alleged value may properly be questioned. Yet if it continues to be employed by a number of careful clinical observers it may have a usefulness that other observers have failed to note. This applies to colon irrigations; the desirable attitude toward which is not exaggerated abuse by those who do not use them or overweening praise by those who do, but a correct estimate of their value and indications.

Such an appraisal is attempted by Dr Frank H Krusen in his article in *THE JOURNAL* of January 11. In large measure I agree with what he says. But as he has quoted me freely may I be permitted to point out what seem to me some erroneous impressions given by his paper?

1. The terms 'mucous colitis' and 'ulcerative colitis' he apparently considers synonymous, for he contrasts my favor of the use of irrigations in mucous colitis with Barger's objections to it in ulcerative colitis. Later he says 'The observations of Barger tend to show that colonic irrigations are contraindicated in 'mucous colitis' and the consensus among experts in the field would tend to support Barger's contentions.' In the article from which this was abstracted (*Chronic Ulcerative Colitis*, *Am J Digest Dis & Nutrition* 1 190 [May] 1934) Barger was not speaking of mucous colitis but solely of ulcerative colitis. Mucous colitis is not ulcerative colitis and, like Barger, I am opposed to the use of irrigations in the latter condition.

In my paper on colon irrigation in *THE JOURNAL*, Feb 27, 1932, I gave several possible uses for irrigations but my employment of them is confined almost exclusively to patients with mucous colitis. Even in arthritic patients I continue their use only if mucous colitis is present. To remove toxic matter my use of them is almost limited to patients with acute or subacute food poisoning. When there is chronic intestinal putrefactive toxemia, more can be accomplished by regulation of the diet and of the bowel movements. The nature of mucous colitis is by no means fixed in the minds of the profession; indeed some consider it a myth, notably Dr A F Hurst of London.

My reasons for believing it a clinical entity and my conception of its nature are given at length in *Medical Clinics of North America* (18 883 910 [Nov] 1934).

2. The author quotes Rankin, Barger and Buie "Almost invariably irrigation with medicated solutions, continued over a time that is long enough to have effect, makes for increased irritation and abdominal discomfort. Tidy has suggested that medicated enemas continued over a period of time would induce colitis in healthy individuals." What do these writers mean by medicated solutions? Are they liquids containing salt, sodium bicarbonate, soap, peppermint, turpentine, silver nitrate or what? Have the authors evidence, not suggestions, that any or all of these liquids produce colitis, and if so under what conditions of use? These questions I ask solely for the sake of truth for like these physicians I am opposed to the use of medicated irrigation fluids. But condemnation of the use of medicated fluids cannot be construed into condemnation of all irrigations. I regularly employ plain water. Physiologic solution of sodium chloride is next best, but I think that it is too readily absorbed, for its use is often followed by the necessity of emptying the bladder two or three times within an hour or two. All colon contents normally contain much water, but no one would suggest that such contents ever resemble physiologic solution of sodium chloride or are isotonic with it.

3. As indicating lack of approval of irrigations by physicians, the author reports extremely few calls for them in his hospitals. I find that in hospitals with a physical therapy department not only is an extra charge made for an irrigation but the patient must be conveyed from the bedroom to the irrigation room under a fixed appointment time. Usually the apparatus is cumbersome and elaborate, and the nurse fills the patient's ears with laudation of the particular method employed. Physicians have stated to me that they do not like such hospital schemes and prefer to have irrigations given in bed with simple apparatus by the patient's nurse. However, judging from my many years' experience on the attending staffs of two active general hospitals the indications for irrigation are rather infrequently encountered in bed patients. Therefore the number of calls for irrigations in a physical therapy department is not a measure of their approval by the physicians of the community.

I am not an irrigationist but a therapist, and my judgment is that simply administered colon irrigations have a definite though limited use in the practice of medicine. This communication is intended as constructive and not destructive criticism of Dr Krusen's paper.

WALTER A BASTEDO MD New York

ATROPINE AND BELLADONNA IN STOMACH DISORDERS

To the Editor—I have read Dr Walter A Bastedo's article "The Value of Atropine and Belladonna in Stomach Disorders" which appeared in *THE JOURNAL*, January 11, page 85, in which he states that 'In single maximum doses by hypodermic injection, atropine may have a limited value in reducing secretion and spasm.'

My interest in the parenteral use of atropine goes back two years, at which time a patient with gastric crisis was being treated. The vomiting had persisted for several days in spite of medication including the subcutaneous administration of atropine but stopped within five minutes after the intravenous administration of 0.6 mg ($\frac{1}{100}$ grain) of atropine. The result was so miraculous that other symptoms thought to be related to the parasympathetic nervous system have been treated similarly.

From 0.4 to 0.5 mg ($\frac{1}{150}$ to $\frac{1}{120}$ grain) of atropine dissolved in about 1 cc of saline solution has been used intravenously.

Phenobarbital sodium (2 grains, or 0.13 Gm) was given at the same time in two instances when the psychic element seemed to be quite prominent. Relief from nausea, vomiting and pain was obtained within two to five minutes in patients with smooth muscle spasm secondary to a peptic ulcer or pylorospasm.

The relief from the intravenous use of atropine has almost been phenomenal with other symptoms thought to be related to the parasympathetic nervous system. Thus the pain in angina pectoris, biliary dyskinesia or that associated with the grasping of a gallstone in the neck of the gallbladder, and ulcerative colitis, the dyspnea of asthma, and, in two cases, cardiac extrasystoles have been stopped. The intravenous atropine has not been effective with pain secondary to coronary thrombosis, infection and necrosis (pancreatitis), or to the presence of a foreign body (common duct stone, hydrops of the gallbladder, ureteral stone). It did not help the pain in one patient who had had an operation for gallstones and who felt that a stone had been overlooked and who subsequently was cured by an exploratory operation (psychoneurosis).

The intravenous administration of the maximal doses of atropine has a definite place in the relief from certain types of pain. It also serves to differentiate similar pains (such as angina pectoris and coronary thrombosis, biliary dyskinesia and common duct stone). It has been given in doses of from 0.3 to 0.6 mg and repeated, if necessary, at fifteen minute intervals until signs of atropinism appeared. It is difficult to explain the discrepancy in the action of such large doses given intravenously and subcutaneously, unless it might be that through the intravenous route the maximum dose is available immediately. No bad effects have been noted in the dosage used.

The use of atropine intravenously in gastric crisis was suggested by Dr. Joseph Earle Moore in *The Modern Treatment of Syphilis*, Springfield, Ill., Charles C. Thomas, 1933.

EARL R. LEHNHERR, M.D., Boston

"IONIZATION TREATMENT OF HAY FEVER"

To the Editor—The report on the ionization treatment of hay fever, by Ramirez (*THE JOURNAL*, January 25, p. 281) should be followed by reports from rhinologists who have had experience with this treatment. The ionization of the nasal mucosa is applied for two conditions—hay fever and hyperesthetic rhinitis. There is now sufficient evidence that in many cases this treatment has merit. Hollender of Chicago has used zinc ionization for perennial catarrh for some years with successful results. His experience has been corroborated by Hurd and myself in New York. At a recent meeting at the New York Academy of Medicine, a report from the Manhattan Eye, Ear and Throat Hospital was most encouraging.

During the 1934 hay fever season I had encouraging results in the treatment of hay fever by ionization. In a summary of the results in forty private cases before the Pan American Medical Association, I concluded as follows: "Although we are satisfied that zinc ionization of the nasal mucosa is worth while, it should be understood that no definite endorsement of the treatment should be given until one has a record of cases extending over a number of years. We are inclined to feel that no promise should be made in any case."

When I returned to America I again used ionization in a number of cases of hay fever. I was amazed and dismayed to find that hardly one case was relieved. It is impossible for me to give any reason. However, 90 per cent of the cases of hyperesthetic rhinitis were relieved.

I have great respect for the allergist. But how many allergists can claim that they have accomplished more than a seasonal

relief in cases of either hyperesthetic rhinitis or hay fever? This does not lead me to write a paper condemning the inoculation treatment. It has its place and I feel sure that ionization of the nasal mucosa has its place also.

HAROLD HAYS, M.D., New York

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

LOSS TO THE COMMUNITY FROM SYPHILIS

To the Editor—Are any figures available to show the economic loss to the community from syphilis? You quote Usilton's statement that over a million patients with primary and secondary syphilis seek treatment yearly. What proportion of these become inmates of insane hospitals and what is the cost of caring for the early and late cases?

CHARLES E. WELLS, M.D., Randolph Mass

ANSWER—References to the economic cost of syphilis, collected from various sources or in the form of original statistics, are given by Thomas Parran Jr. (*Public Health in New York State*, published by the State of New York Department of Health, Albany, 1932, pp. 236-238) and by J. H. Stokes (*Modern Clinical Syphilology*, Philadelphia, W. B. Saunders Company, 1934, pp. 1103-1105 and 1309-1310). Parran says:

Based on an estimated attack rate of syphilis of 4.4 per 100,000 for upstate New York and 7.8 for New York City there would be 81,000 new infections per year. A moderate estimate of the cost per year for treating adequately a case of early syphilis is \$200. Hence adequate care for syphilis in New York State would cost around \$16,000,000 a year.

Outpatients—At the present time upstate clinics are admitting new cases at the rate of 5,000 annually and administering about 150,000 treatments at a moderate estimate of the cost at \$2 per treatment this would be a \$300,000 service.

Institutional—In state institutions there are approximately 2,000 patients suffering from general paralysis. The cost of building and equipping state institutions is approximately \$4,000 per capita. Thus facilities in state institutions for the care of cases of general paralysis are valued at about \$8,000,000. The cost of maintenance not including administrative cost or charges on investments is approximately \$400 a year per patient. The annual cost for the maintenance of 2,000 cases of general paralysis would be approximately \$800,000.

The above estimates represent only a small part of the economic loss of syphilis. Loss of income because of disability, hospital costs aside from mental disease hospitals and loss because of the shortened life span of those infected represent an enormous burden the total of which cannot be accurately estimated.

Stokes says:

Williams estimated that ten men insane from syphilis represented a net loss based on life expectancy of \$212 to \$248 in earning capacity and a cost to the state of Massachusetts of \$39,312. According to the census of 1910 there were 180,000 insane persons in the United States. Estimating 12 per cent of insanity to be due to syphilis and the experience of Massachusetts to be applicable to the country as a whole the economic loss in earning capacity and cost of care on the score of a single item in the total bill of syphilis would approximate \$467,000,000.

Parran estimates that the cost of adequately treating syphilis as a public health problem would be \$0.88 per capita annually. That the loss due to the shortened span of life of patients with dementia paralytica represents a cost of \$1.20 per capita and the loss due to death from other forms of syphilis represents more than \$10 per capita for the population of this country.

Figures on the cost of treating syphilis vary widely with comparatively recent publications on the subject by Keidel, Bromberg and Davis. Since such treatment costs represent forms of economic loss, the following summary of these authors' observations is quoted from Stokes:

An estimate of \$500 for the treatment of a syphilitic infection to standstill or cure has been followed by Keidel's figures of \$180 as minimum private rates for a period of fifteen months and an average rate of \$650. Two studies by Bromberg and Michael Davis indicate that private care ranges from \$273 to \$723 per case with a maximum of \$1,425 under individual private care. By an effective form of organization the rates can be reduced to \$135 with \$300 a fair average figure. The actual cost of treating a patient at the Johns Hopkins Hospital for syphilis amounts to \$1.03 per visit and with an average total of twenty-six visits over a period of twenty-seven months the patient with early syphilis must meet a cost of \$78.

With reference to the prevalence of neurosyphilis among inmates of insane hospitals, Parran (p. 237) estimates that dementia paralytica develops in from 2 to 5 per cent of the cases of syphilis. The average annual admission to state insti-

tutions for mental disease in up-state New York total 856 cases from this cause Stokes (p 1103) quotes approximately the same figures for the incidence of dementia paralytica from Mattauschek and Pilcz, Fischer, Pick and Bandler, and Furbush. The Metropolitan Life Insurance statistics quote the incidence of tabes and dementia paralytica as from 131 to 166 per hundred thousand. Kirby gives the hospital admissions for dementia paralytica in New York State over a period of years as 84 per hundred thousand. Marie gives the incidence of dementia paralytica in Egypt as 55 per hundred thousand. As a factor in neuropsychiatric work, dementia paralytica is rated by May as the cause of 11 per cent of 70,000 first admissions to forty-eight hospitals in sixteen different states in this country. Richards, in White and Jelliffe's textbook (quoted by Southard and Solomon), states that dementia paralytica constitutes from 5 to 7 per cent of all military cases of mental disease in the French, German, American and Russian armies.

The most recent figure released by the United States Public Health Service, apropos of the inquirer's quotation of figures of "over a million patients with primary and secondary syphilis seeking treatment yearly," is 518,000 new cases for 1934.

CHRONIC OSTEO ARTHRITIS

To the Editor—A man aged 60 complains of a snapping or cracking in his neck when he turns his head from side to side. This condition has existed for several years but has been more noticeable lately. Recently the back of his head and neck have been sore constantly. Examination reveals very slight tenderness on pressure over the cervical spines and the muscles to either side. When he turns his head the cracking sound is distinctly audible. There is no history of trauma and no stiffness or limitation of motion. Physical examination is otherwise essentially negative. Would roentgen rays be likely to reveal any positive changes? I would appreciate suggestions as to possible causes and method of treatment.

MD, New York

ANSWER—Many elderly people complain of these symptoms. The cause is almost invariably a low grade chronic osteoarthritis of the small lateral articulations of the cervical vertebrae. These are true joints, with capsule, ligaments, articular surfaces, synovial membrane and synovial secretions and they are affected by arthritis in the same manner and with the same results as any other joints.

In many cases, roentgenograms will show characteristic "lip-ping" of the bodies of the vertebrae, these osteophytes being most noticeable in the anterior edges in the lateral view. Such lip-ping also occurs in the actual articulations but cannot be seen as well in the roentgenograms.

When the head is rotated, crepitation occurs exactly as it occurs in arthritic knee joints.

The treatment of the condition is the removal of any obvious focus of infection, plus improvement of the general health and resistance. The use of autogenous or stock vaccines is still under discussion. Foreign protein injections have their advocates.

Moist, hot fomentations locally and acetylsalicylic acid will tend to relieve exacerbations. In severely painful cases, a Thomas collar or a well fitted steel and leather apparatus to immobilize the head and neck will afford immediate comfort. It need not be worn continuously.

The general tendency is toward improvement in most cases under treatment, with a high percentage of symptomatic cure.

FRACTURE OF THE JAW

To the Editor—An infected fracture of the inferior maxillary bone is hard to get and hold in place by various dental methods. There is an external fistula which has drained pus for several weeks. Dilute solution of sodium hypochlorite when introduced into the external fistula passes into the mouth by the teeth. Some small slivers of bone have been discharged from the external fistula. One passed up at the side of or between the front teeth. If no other method will hold the jaw together is it good surgery to drill holes into the jaw and wire it when pus is present? If not how soon will it be considered safe to do such an operation? The fracture is about 2 inches to the left of the median line. The external fistula goes to bone at the point of fracture.

MD New Mexico

ANSWER—In the case cited there are two problems to be considered. First the reduction of the fracture with the restoration of normal occlusion and second the control of the infection. The simplest and best method of reducing the fracture and restoring the normal occlusion is by the attachment of an Angle's ribbon arch to the upper teeth, using ligature wires on the bicuspids and molars and silk ligatures on the incisors. A similar piece of Angle's ribbon arch is attached to the lower

jaw, on the short fragment only, in the same manner. Small orthodontia rubber bands are then attached to the wires in the two jaws, and it will be found that by elastic traction the displaced fragment will be quickly drawn into place and held with complete immobilization. This method not only corrects the fracture but gives the patient considerable freedom in jaw movements, permitting the taking of soft foods and proper cleansing of the mouth.

The fistula should be irrigated once a day with an iodosaline solution, which is easily made by taking as a base physiologic solution of sodium chloride and adding thirty or forty drops of tincture of iodine to a glassful. Continued suppuration in a compound fracture is almost always due to dead bone. A roentgenogram should be taken to determine this point. It is sometimes advisable to allow these small sequestrums to work to the surface, where they can easily be removed, rather than under take a more pretentious operation.

The management of jaw fractures is outlined in THE JOURNAL, May 19, 1934, page 1655.

The proposed wiring of the bones should not be undertaken because in the first place it does not insure the restoration of occlusion and, because of the infection, the wires usually have to be removed, leaving a bad scar. The simple method of elastic traction will insure a perfect occlusion, requiring no operation and no anesthetic.

NONALLERGIC SOAP

To the Editor—Will you please inform me as to the name of the manufacturer of a nonallergic soap? S. E. WITT, MD, New York.

ANSWER—There probably is no such thing as a strictly nonallergic soap. Although every kind of soap contains one or more ingredients that sometime or other will cause trouble to the skin of certain individuals.

Some soaps, especially those impregnated with chemicals seem to be more harmful than the milder ones but even the mild ones may cause some trouble.

The following materials, which are contained in some soaps have already been reported as causes of contact dermatitis. This list is by no means complete: oil of bergamot, boric acid, borax, cottonseed oil, formaldehyde, hydrous wool fat, lilac, saponated solution of cresol, mercury compounds, orris root, quinine, resorcinol, rice, phenol, coconut oil.

In general, it would seem safe to avoid highly scented or highly colored soaps. There seems to be some evidence that shaving soaps are less irritating, on the whole than are the ordinary toilet soaps.

FECAL FISTULA

To the Editor—What is the treatment, medical or surgical of a fecal fistula that developed ten days following a resection of a sigmoid carcinoma with primary anastomoses? Kindly outline the immediate and remote treatment.

MD New York

ANSWER—The immediate treatment of a fecal fistula is directed primarily toward prevention of irritation and excoriation of the skin. The secretion of a fecal fistula following resection and anastomosis of the sigmoid, being in the left half of the colon, is more or less formed and not liquid. It is necessary, therefore, to change dressings only several times daily to remove the accumulated fecal discharge and cover the surrounding skin with a protective dressing of petrolatum, zinc oxide, 3 per cent tannic acid, powdered kaolin, or kaolin glycerin paste. If there is infection of the wound with redness and induration of the skin, this must be treated first by hot dressings and provision for adequate drainage.

The fistula itself, once established may be curetted and cauterized with phenol, silver nitrate, the actual cautery or surgical diathermy to destroy the granulations or epithelium of the sinus. This is often sufficient to produce permanent closure. Injections of irradiated petrolatum or Beck's paste followed by irradiation have been reported successful in effecting closures.

Almost a third of the fistulas will heal spontaneously within six to eight weeks. The fistulas that persist do so chiefly because of two factors: obstruction within the bowel distal to the sinus due to a spur or growth and lining of the tract by epithelium or mucous membrane. These persistent fistulas require surgical excision. In deciding when a fistula should be closed one should be guided by the amount and character of the drainage, the inconvenience it causes, the condition of the surrounding skin and subcutaneous tissues and the patient's general condition. Approximately three months may be permitted to elapse.

The operative removal of a fistula consists in isolation of the whole tract from the skin to its entrance into the intestine, its separation from the skin and the intestine, and the closure of the resultant defects in the intestine, abdominal wall and skin.

The fistulous tract can be more easily followed if it is filled with an indigo carmine or methylene blue solution. During the operation the introduction of a probe facilitates the finding of the tract. As a rule however it is not difficult to trace the fistulous canal, because it is clearly differentiated from the surrounding tissue by its firmness and fibrous structure.

TIC DOULOUREUX

To the Editor—A white woman aged 64 has attacks of very severe knifelike pains in the right side of the head. These seem to radiate up from the right side of the neck where she has a large tumor. She has had an enlarged thyroid gland since she was 10 years old. Twenty years ago the enlarged gland was given eight roentgen treatments and became smaller. She has been feeling well till this year when she began having these very severe headaches. Drugs other than morphine seem to give no relief. The blood pressure is 190 systolic 100 diastolic but during an attack it goes to 220/100 and the heart becomes very irregular in rate and rhythm. Following an attack of this severe headache she will vomit consistently for three or four days vomiting as little as a teaspoonful of water. Examination of the neck reveals an enlarged thyroid extending from the left side across the neck to the right and the growth extends to the angle of the jaw. Pressure on the right side causes pain and continued pressure will set off an attack of the severe headache. The eyegrounds show multiple areas of retinal degeneration with degeneration in the macula of the right eye. (She constantly sees a dark spot floating in front of the right eye more so during an attack of headache.) The visual fields are contracted in both eyes. There are no choked disks. The headaches come about every five or six days. Please suggest a possible diagnosis and cause of the condition also drug treatment to control the headaches and finally treatment if any to help this patient.
MD Pennsylvania

ANSWER—From the description given it would seem that the pain is of the nature of a tic douloureux rather than of a headache. For this reason a description of the distribution of the pain would have value. Study of the condition of the pupil during an attack should be made and observations of the relation of the increased hypertension to the attack, that is, whether it precedes or follows the onset. It is possible that as a result of the roentgen treatment there has been caused a sclerosis of the tumor tissues, with involvement of the carotid sheath and sympathetic fibers and perhaps also of the vagus. Increased intracarotid pressure like pressure on the tumor from without, from any cause might then cause irritation of the sympathetic fibers and thus give rise to pain. If further study gives any support to this hypothesis, the possibility of some form of sympathectomy should be considered. Whether any such operation is possible in this case must be determined after careful general and local examination. Consultation with an experienced neurosurgeon is certainly indicated.

TINNITUS AND VERTIGO

To the Editor—A man aged 57 has a great deal of trouble with dizziness. He gets attacks of tinnitus especially when he mounts a step ladder but he may have them when he is walking around and even while he is lying down. The duration of this trouble has been about a year and a half. Onset was gradual and the attacks have become more frequent and severe. There are no other complaints. He does not get nauseated nor does he have any headaches. Simply when he turns his head quickly the dizziness comes on and passes away in a few moments. The physical examination is essentially negative. He wears glasses. There is no nystagmus. The blood pressure is 140 systolic 82 diastolic. The chest and heart are normal and the urine and blood show no abnormalities. The Wassermann reaction is negative. There is no diminution in hearing. My impression is that the seat of the disturbance is in the labyrinth. Do you think my diagnosis is correct? What bothers me is the treatment. I have prescribed phenobarbital one-half grain (0.03 Gm.) twice a day and thyroid 1 grain (0.065 Gm.) daily which seems to have benefited the patient to some extent. I would appreciate any suggestions as to treatment.
MD Minneota

ANSWER—It is quite probable that the disturbance in this case originates in the labyrinth as suggested by the correspondent. The exact nature of the lesion however cannot always be determined but it may be of a vasomotor character. In some of these instances there is an allergic factor therefore it would be advisable to have complete tests made to determine whether any protein sensitization is present. Otherwise the use of a mild sedative such as has already been employed is often of benefit. So far as the tinnitus is concerned that also may be due entirely to an inner ear or auditory nerve involvement and in such a case the use of sedatives

is likewise sometimes beneficial. On the other hand, if there is any involvement of the middle ear or eustachian tube the application, after cocainization, of 1 per cent silver nitrate to the pharyngeal orifice of the eustachian tube several times a week sometimes diminishes the tinnitus. Years ago the late Dr. B. Alex. Randall of Philadelphia reported good results in cases of tinnitus from the application of 1 per cent ethylmorphine hydrochloride to the eustachian tube by means of a catheter. Tinnitus is only a symptom that may be due to lesions in the eustachian tube, the middle ear or the inner ear and auditory nerve, but the factors that are directly responsible may be not merely local but systemic, either because of changes in the blood itself, hypertension or subhypotension, or toxemias of various kinds arising from infection of the tonsils, teeth, gallbladder or gastro-intestinal tract. Careful study of the whole body is therefore needed in some of these instances, and consequently despite all efforts some cases respond poorly to all forms of treatment or medication, whereas others are quite amenable.

ALLERGIC EDEMA OF SCROTUM

To the Editor—Information concerning the possible cause and treatment of recurring attacks of edema of the scrotum will be appreciated. A man aged 49, married, enjoyed excellent health until the past eighteen months when he began to have attacks of edema of the scrotum, coming on every two or three months and usually clearing up in the interval. They are of very sudden onset and never were associated with pain, itching or general symptoms until the last two times, when there have been general malaise and fever. The edema seems to involve only the skin and is symmetrical. The general examination is normal, including the serum Wassermann reaction. The genitalia are normal. There has never been fluid inside the tunica. There has never been a hernia on either side. He has had no operations except tonsillectomy and excision of fistula in ano. For many years he has had what has been diagnosed as eczema of the scalp and occasionally of the back. There is no other allergic history. He has never had a venereal infection. These attacks are not related to intercourse.
MD Texas

ANSWER—On the information outlined the most likely diagnosis would be angioneurotic edema. The fact that the swelling is confined to the scrotum is quite in line with other cases of recurrent localized allergic swellings, such as one eye, the tongue, or a hand. The presence of eczema of long duration lends additional credence to the possibility of an allergic etiology for the edema.

The causes are varied and numerous. Food allergy is one of the most common. Drug sensitivities should be investigated. Contact allergens should also be considered. Allergic swellings on the basis of fungous sensitization secondary to trichophyton or monilia infection should be ruled out. Is it possible that the "eczema" has ringworm as an underlying basis? Finally, the question of focal infection needs attention, since many instances of angioneurotic edema are due to infections in the gallbladder, tonsils, teeth, prostate and disturbances in the gastro-intestinal tract. By history, examination, skin tests and elimination diets the etiology may be ascertained.

The treatment will, of course, be dependent on the etiologic factor that may be found. Until such time as the cause can be located or in the event of failure to determine such a cause, other therapeutic procedures may have to be tried. Peptone, 0.5 Gm. orally one-half hour before meals, is helpful in cases of food or gastro-intestinal origin. Parathyroid extract-Hanson (10 units) hypodermically, every day or two and then less often, will frequently control the condition. Autohemotherapy with from 10 to 20 cc. of whole blood is often successful. Ephedrine may control the swelling temporarily.

DIAGNOSIS OF PARALYSIS AGITANS

To the Editor—What does the spinal fluid show in cases of paralysis agitans? Does laboratory examination reveal any other characteristics? Please omit name.
MD Illinois

ANSWER—There are no characteristic spinal fluid changes in cases of paralysis agitans. The fluid is clear and is usually under slight pressure during the excitatory stage. There are no abnormal cells or unusual chemical changes in the fluid.

There are no definite laboratory observations in cases of paralysis agitans except for the pathologic changes and the associated conditions which may simulate Parkinson's disease. The pathologic changes usually affect the basal ganglia. Persons are attacked with this disease usually between the ages of 50 and 70 years. There is a degeneration within the striate body and the globus pallidus, causing atrophy of the ganglion cells and their fibers.

There are other forms of parkinsonism. Manganese produces severe degeneration in the basal ganglia. Carbon monoxide poisoning frequently attacks the basal ganglia, particularly

the anterior ends of the globus pallidus. The gas also affects other structures in the brain as well. The laboratory examination here consists of carbon monoxide determination of the blood. Trauma to the brain may attack the basal ganglions and produce the syndrome of paralysis agitans. Hemorrhage or softening leads to the formation of gross lesions in the basal ganglions.

EFFECTS OF NEOARSPHENAMINE

To the Editor—Is there any difference in the systemic effect of neoarsphenamine given intravenously and intramuscularly? The vision of a young woman with well marked optic neuritis is reduced to hand movements at 20 feet. To my surprise her physician told me that she was giving her neoarsphenamine intramuscularly. She has several hard and painful lumps on her back, the site of injection. I have never heard of neoarsphenamine being injected intramuscularly and am wondering if there is anything unusual especially as regards the eyes when so given.

O M CRENSHAW M.D. Lebanon Ky

ANSWER—Few syphilotherapists in this country have had experience with the intramuscular injection of neoarsphenamine because the local reactions from the mode of treatment are as a rule so severe that but few patients will tolerate more than one injection. Not infrequently necrosis and ulceration follow the intramuscular injection. In the early experience with neoarsphenamine many injections were given intramuscularly and many of these patients still carry these infiltrated nodules in their buttocks or intrascapular regions at the site of the injections. Reports from Europe indicate that the therapeutic use of the intramuscular injection of neoarsphenamine has a more pronounced effect on the serum reaction than does the intravenous injection. Colonel Harrison of London and Dr R L Sutton of this country have been advocates of this form of administering the neoarsphenamine, and a discussion of the mode of treatment will be found in the sixth edition of Sutton's book on 'Dermatology'.

PERFORATION OF NASAL SEPTUM

To the Editor—A white girl aged 12, came to me in August 1935 with a perforation in the anterior part of the nasal septum the diameter of which is 3 or 4 mm. In February 1935 she had severe lobar pneumonia from which she has recovered. Her mother says that ever since the pneumonia the girl has had trouble with her nose. When the perforation occurred is not known. It is painless and bleeds rather easily. The tissue around the perforation looks healthy. The general condition of the child is negative. There is no history of tuberculosis or syphilis either in the patient or in her family. The Kahn test for syphilis in the patient was 1 plus the blood of her father was negative and her mother's was reported doubtful probably negative. Scrapings from the perforation were negative for acid fast organisms. I hesitate to treat this girl for syphilis with no further evidence than I now have. I would appreciate any suggestions as to the further management of this case. What is the accepted treatment for this nasal perforation due to tuberculosis?

M D Colorado

ANSWER—From the history as given and the site of the perforation in the anterior cartilaginous portion, it is most likely that the lesion is a traumatic (nontuberculosis and non-syphilitic) one. Tuberculosis of the septum is exceedingly rare. Syphilis of the septum nearly always involves that part of the septum which contains bone in addition to cartilage, namely, the posterior half. The history that this condition followed a severe attack of pneumonia probably points to the time of onset, crusting may take place at these times, the patient is too sick for the proper nasal hygiene and may also pick the nose frequently. Under the circumstances, the simplest treatment here would be the best. The nose should be kept well lubricated with an oily preparation or petrolatum to reduce crusting and the margins of the perforation should be touched up with some such preparation as dilute silver nitrate or dilute trichloroacetic acid.

OBLITERATING VASCULAR DISEASE IN AGED

To the Editor—A man aged 68 has had a definite diagnosis of Buerger's disease. About a week ago when a blood count was made I found that he had an erythrocyte count of 5 770 000 and hemoglobin 99 per cent. Is this due to the disease or is he experiencing the beginning of polycythemia? I may also mention that for the past two weeks he has been suffering from dyspnea vertigo weakness and loss of appetite from which patients with polycythemia suffer.

C O ANDERSON M.D. St. Petersburg Fla

ANSWER—A man, aged 68 who has occlusion of the major arteries of the extremities is more likely suffering from arteriosclerosis obliterans than thrombo-angitis obliterans or Buerger's disease. The occlusive process is a bland noninflammatory thrombosis in an arteriosclerotic vessel. In some patients with advanced forms of arteriosclerosis there is evidence of concentration of the blood, as demonstrated by moderately elevated

blood counts and by an increase in the concentration of hemoglobin and an increase in the percentage of cells as determined by the hematocrit. The blood changes are those of a relative polycythemia, not a true polycythemia. The spleen is not enlarged and the veins in the retina are not engorged, nor are the mucous membranes excessively red. It is likely that the symptoms of which this patient complained were due to arteriosclerosis of the cerebral and cardiac arteries rather than polycythemia. The cause of the blood concentration in arteriosclerosis is not clear. It was first described by Galsbush in association with hypertension.

STERILITY

To the Editor—Among my patients I have a young couple who are desirous of having a baby but after two years of trial have been completely unsuccessful. The woman is 28 years of age and states that she has had no venereal infection of any sort. The menstrual periods have always been regular and attended with cramps until a few years ago. Vaginal examination reveals a normal uterus normally placed. Smears of the vaginal tract show no gonococci but the smears are strongly acid to litmus paper. There is no abnormal discharge. Her husband is in good health and up until a few years ago was a rather heavy indulger in alcohol. There is no history of venereal infections. Microscopic examination of the semen shows a fair rate of motility but many of the sperm cells are motionless. (The specimen was examined soon after intercourse.) There is no hypospadias. I have advised abstinence for a period of a few weeks and then the use of alkaline douches just before intercourse. Can you advise any other methods I may suggest should these procedures fail? What is the present consensus as to which period in the menstrual cycle is the optimal time for conception to take place?

M D Ohio

ANSWER—A thorough investigation in accordance with the plan of Meaker will probably reveal one or more causes for reproductive failure. A postcoital test of the spermatozoa should be made from the vaginal vault and cervical canal, if a large number of living spermatozoa are recovered from the cervix, a test for the patency of the fallopian tubes should be made. If the results of these tests are satisfactory, the couple should be advised to hold intercourse at such time as is most likely to result in pregnancy, namely, in the mid month period. It is the present consensus that ovulation occurs from fourteen to fifteen days before the onset of menstruation. It is also believed by many that the ovum is susceptible of being fertilized for but two days and that a human spermatozoon can fertilize the ovum for no more than three days, therefore repeated cohabitation in the midmonth week appears to be logical advice.

SEXUAL HYPERSENSITIVENESS WITH COLON SPASTICITY

To the Editor—A man aged 40 unmarried has the following complaints: 1 Sexual hypersensitiveness. Since puberty he has been uncomfortable in the presence of women and has an erection. He therefore avoids riding in trolley cars and any other contact with women. It has had a serious economic effect. 2 A spastic colon corroborated by roentgen examination. When the colon symptoms are worse he feels sexually more uncomfortable. (Is his sexual symptom due to the colon or is it a separate condition?) 3 Weakness. He gets up tired in the morning cannot do strenuous work and gets tired early in the evening. He has had silver nitrate instillations in the urethra. The colon has been treated by a smooth diet rest and antispasmodic drugs. He would be satisfied if his sexual condition was relieved. This would enable him to do his work better and change his outlook on life. Please give your suggestions. He requires ten hours of sleep. His father sleeps as soon as he sits down even at meals (probably narcolepsy). Kindly omit name.

M D Pennsylvania

ANSWER—Sexual complaints such as those described are much more common in single than in married men. They bear evidence of nervous sensitivity. The so called spastic colon is another indication of hypersensitiveness of the nervous system. A condition in which much intestinal spasm and abdominal discomfort prevail is better known as an "irritable colon" associated with nervous fatigue. Both of these complaints at once suggest that the condition is not primarily one of malfunction of the intestine or the sexual organs but rather a part of a systemic disturbance. The sexual dysfunction, intestinal irritability and easy fatigue all point to a highly sensitive and easily disturbed nervous system.

Treatment should not be directed toward the relief of any of these symptoms singly but rather to the relief of the nervous fatigue. This will be best accomplished by adopting a well ordered program of rest and restful recreation, plenty of outdoor exercise, fresh air and sunshine, and some program of recreational diversion that will be pleasant for the individual. There are no drugs advocated for these conditions which offer more than transient relief.

PERSISTENT SUPERFICIAL INFECTION

To the Editor—A youth aged 17, injured the anterior surface of the right lower leg while playing football five years ago. The wound consisted of a rather insignificant abrasion which however developed into a severe infection with a high fever and an abscess formation in this vicinity which required drainage. There are now two scars about the size of a half dollar (30 mm). I first was called to see him about two years ago when he complained of pain in the region of these scars. He had a temperature of 104 F and there was considerable redness around the area with enlargement of the inguinal glands. The process subsided with rest, elevation and heat. This however recurs about every four to five months sometimes following a slight bump and sometimes without any trauma. Roentgenograms of the tibia and fibula are negative and the serology is normal. A careful search was made for any foci of infection but none were found. This trouble caused him considerable economic loss and any advice that you can offer on how to rid him of it will be appreciated.

M D Ohio

ANSWER—This patient's history suggests that there are virulent bacteria still present in the tissues which are reactivated from time to time and cause active inflammation. Although it is unusual for bacteria to remain in the tissues as long a time as is indicated by this patient's history, there is abundant evidence available to indicate that bacteria can remain viable in the soft tissue for over a year and in bone for a considerably longer period.

There is no direct method of attack available in the treatment of such conditions. To carry out any surgical operation would be a certain way of stirring up trouble. The patient would be best advised to do everything possible to safeguard his general health and to avoid any local traumatism or injury about the site of the original wound.

CONTROLLING ETHYLENE DANGERS

To the Editor—Will you please advise the general policies followed for having x-ray units in the surgical department where ethylene gas is used? We are contemplating revamping our surgical suite and if it is an acceptable policy to do so we are considering having our cystoscopic table with a Kenetron transformer and control stand in a room adjoining one of our major operating rooms. This room to be used in combination with our fracture service. We have a fracture table and have just recently purchased a shock proof and ray proof mobile x-ray unit. Any information you may give us with reference to general policies followed in having x-ray service (such as I have outlined) in the surgical department where ethylene gas is used will be appreciated.

RALPH M HUESTON Joliet Ill

ANSWER—The most conservative and safest practice adopted by those with experience is to avoid ethylene oxygen anesthesia under conditions in which the use of an open flame electric cautery, radio knife or any electric sparking device is indicated. As the inquirer undoubtedly knows, intravascular explosions may have occurred during fulgurations of the urinary bladder owing to the liberation of explosive gases even when the anesthetic mixture used was simply nitrous oxide-oxygen. Had ethylene-oxygen anesthesia been used, every one would have attributed the explosion to that anesthetic. Everything considered, ethylene-oxygen ether or nitrous oxide oxygen-ether anesthesia should not be employed when the danger of ignition of these inflammable mixtures by sparking electrical apparatus is even remotely possible. Nitrous oxide oxygen is the only positively safe anesthetic to use under these conditions.

PHLEBITIS AFTER GONORRHEA

To the Editor—Sept 12 1934 a patient came in with all symptoms of an acute gonorrhea such as frequency, burning and a discharge. Two weeks later he developed a perirethral abscess which was incised and drained. This was followed with considerable edema of the foreskin which was incised several times. October 25 the left testicle began to swell accompanied by severe pain and several days later the left inguinal gland became swollen. Two weeks after the testicle began to swell the left leg became painful especially around the thigh. The whole leg down to the ankle became edematous to approximately one and one-half times the normal size. There was no pain on motion and no pains in the joints. The patient was in bed about seven weeks from October 25. In the meantime the discharge was continually present and positive until May 13 1935 when on resumption of urethral insufflation sounds and massages the discharge became negative and stopped. Now after eight months the pain in the leg is less severe but still present and accompanied by a slight amount of edema. The veins around the posterior surface of the knee are dilated and prominent. What line of treatment would you suggest for the leg condition which is in my opinion a gonorrheal phlebitis? Kindly omit name.

M D New York

ANSWER—The swelling and pain in the legs is in all probability due to phlebitis the origin of which may have been gonorrhea although this is not common. Rest, elevation and the application of moist heat plus the internal administration of iodides are indicated.

Medical Examinations and Licensure

Book Notices

Obstetrical Practice By Alfred C Bec. M D Professor of Obstetrics and Gynecology Long Island College of Medicine Cloth Price \$7 Pp 702 with 1,043 illustrations Baltimore Williams & Williams Company 1935

This new textbook on obstetric practice is presented by a prominent educator in this field. His pedagogic skill is amply evidenced by the clear, logical presentation of his subject to the student and young practitioner. The various chapters present chronologically the story of the various birth processes and their pathologic complications. The ideas are in line with modern scientific advances. All debatable, questionable or theoretical ideas have been omitted for the sake of conciseness. The chapter on antepartum care covers the field completely, emphasizing the great value of this form of prophylactic obstetrics. The mechanism of labor in all the varieties of presentation and position are thoroughly discussed and profusely illustrated. The author feels that a proper understanding of this subject will result in fewer pathologic conditions, with the resultant decrease in maternal and fetal mortality and morbidity. For the same reason a long chapter is devoted to a complete discussion of the medical and surgical complications of pregnancy. There is a lack of relative value in the space devoted to various subjects. Thus one finds forty pages devoted to an excellent discussion of face presentation, which, according to the author, occurs once in 250 labors, while thirteen pages are devoted to a too brief discussion of all the toxemias of pregnancy, and eleven pages to the ever increasingly important problem of abortion. The chapter on operative obstetrics is placed at the end of the book. The various operations are described briefly, although carefully illustrated, emphasizing the view that operative obstetrics should be reserved for the specialist who has had additional training. All the chapters are profusely illustrated. The drawings have been done by the author himself and retouched by an artist. Their uniformity, clarity and number do much to help the teaching value of the text and improve greatly the general appearance of the book. Throughout the book one finds pictures and short biographies of the many interesting personalities that have slowly evolved the science and art of obstetrics. An excellent, selected bibliography follows each chapter. This book can be heartily recommended for students and young practitioners.

Lactobacillus Acidophilus and its Therapeutic Application By Leo F Rettger Ph D LL D Professor of Bacteriology in Yale University Maurice N Levy M D Louis Weinstein Ph D and James E Weiss Ph D Cloth Price \$2.50 Pp 203 New Haven Yale University Press London Oxford University Press 1935

This book should be good, seeing that for twenty years the senior author has been studying intestinal bacteriology and particularly the problem of implanting acidophilic organisms in the bowel.

It is interesting now to learn that *L. bulgaricus*, which for so many years was sold widely and bruted about as a wonderful rejuvenator of mankind, not only does not become implanted in the bowel but actually is rapidly destroyed there. Surely the physician who knows anything about the history of therapeutics will always outdoubt St Thomas when there comes to his desk the first enthusiastic description of marvelous cures obtained with some new drug and as some wag once advised, he will hurry to use the new drug while it is still curing. How annoying it must be to the men who have bragged about a wonderful new cure for let us say, uricæmia, to have some pharmacologist come along and show that the drug is really a mild emetic.

Dr Rettger's enthusiasm is all for *L. acidophilus* which he is sure can be implanted in the bowel under certain definite and essential conditions. In the first place enormous numbers of active living bacilli must be given. According to Rettger most of the preparations on the market contain only a few half dead organisms. But even if the bacteria in the little tablets and bottles were all viable there would still be too few to make any change in the intestinal flora. In the second place, the strain used must be one that is adapted to life in the intestine, and in the third place, the culture must not have been maintained too

long on artificial mediums. The bacterium is one that is highly adapted to its natural medium, and it loses this specificity when, after several transplantings, it learns to live in the test tube. Finally it is essential that from 200 to 300 Gm of dextrin or lactose be given daily so as to modify the pH of the colonic contents.

As Rettger says, in their attempts to use acidophilic bacteria therapeutically few physicians have taken the trouble to fulfil all the necessary conditions, and as a result there has "been an undermining of confidence in the principle involved."

Another great difficulty arises when one comes to the matter of choosing patients suitable for this type of treatment. The reviewer must admit that he has always been much puzzled to know what type of patient would most probably be helped. He has never been able to learn enough about the intestinal flora to know when he wanted it changed or how he wanted it changed. The wise physician does not want to burden people with a troublesome and expensive type of treatment unless there is a large probability that it will do them some good. The writer of this review has found it possible to try out lactobacillus implantation only when he could secure the help of a trained bacteriologist. First, much time had to be spent in maintaining active cultures of an organism which is often hard to grow. Secondly, the milk had to be sterilized and then heavily seeded with the lactobacillus. Finally the patients had to go to the trouble of sending to the laboratory at frequent intervals to get their supply of the product.

When a mountain has to labor to this extent, it usually wants to know what kind of a mouse is to be brought forth. According to the book before us, three out of four of a few patients with simple constipation were helped, and this improvement lasted for from twelve to sixteen weeks following discontinuance of the treatment. Good results were seen also in a few patients with "constipation with biliary symptoms," whatever that means. Three out of four patients with mucous colitis were helped, and seven out of eight patients with ulcerative colitis showed improvement in spite of the fact that in none of them was there an implantation of the lactobacillus. Patients with mucous colitis and ulcerative colitis received benefit only so long as the treatment was being carried out.

We of the medical profession should feel deeply indebted to Dr. Rettger for debunking this form of treatment, which has been so badly misrepresented since the days of Metchnikoff and for showing us how useless it is to give lactobacilli unless the procedure is carried out by experts who will check every stage to make sure that they are doing what they planned to do. Finally we must thank Rettger for his frankness and honesty in saying that, so far, the treatment has been found useful temporarily in such illnesses as constipation and mucous colitis, which can be controlled fairly well in simpler and much cheaper ways.

The Single Woman and Her Emotional Problems. By Laura Hutton, B.A. M.R.C.S. L.R.C.P. Physician, Institute of Medical Psychology. With a foreword by David Forsyth, M.D. D.Sc. F.R.C.P. Cloth. Price \$2. Pp. 151. Baltimore: William Wood & Company, 1935.

This little book should be in the library of every physician, psychologist, sociologist, teacher, clergyman, in short, all those who come in mental contact with the large and increasing class of women whose problems stimulated Dr. Hutton to write the book. Not only teachers and advisers can profit from a careful study of this short, concise, well written manuscript but there are few women who could not profit through assimilating some of Dr. Hutton's sympathetic objective and accurate analysis of the reality situations to be faced, the need for help and guidance to these women who are intentionally or unintentionally single. In the preface Dr. Hutton says "Explanations of the psychological meaning of certain types of behavior or symptoms need always to be approached with the utmost care and gentleness—sympathy, understanding and respect for personality above all undisturbed by any fear or condemnation of sexual manifestations in whatever guise they may appear are essential and this principle holds throughout whether we are dealing with physical symptoms which are recognized as being expressions of emotional and particularly psycho-sexual conflicts and repressions or with explicit psychological difficulties." Dr. Hutton does just this lucidly, clearly and in a frank,

straightforward manner. The book contains five short chapters devoted chronologically to (1) the single woman of today—a historical and present-day analysis of the situation, (2) emotional friendships and some of the psychologic problems involved—a discussion of normal and abnormal friendships among women, (3) sexual problems—those confronting the single woman, (4) sexual inversion, (5) adjustments. Dr. Hutton quotes or refers to several well known psychoanalysts and gives credit to their views. The book is in no way dogmatic or critical unless it be of the adviser and teacher who is utterly lacking in insight and attempts to be pedagogic rather than understanding and unbiased. Dr. Hutton is an English physician and while the book is primarily written for and about the English situation, the problems discussed are equally relevant in this country.

Précis de chimie biologique médicale. Par Paul Cristol, professeur de chimie biologique et médicale à la Faculté de médecine de Montpellier. Cloth. Price 80 francs. Pp. 638 with 13 illustrations. Paris: Masson & Cie, 1935.

This is a good textbook of biochemistry for medical students. In the introduction the historical aspect is first emphasized and the relation of biochemistry to various interests is briefly referred to. The first chapter presents elementary information on the physical chemical relations, such as ionization, osmotic pressure and the colloidal state. A chapter on elementary composition contains some interesting data on the quantitative distribution of inorganic constituents. After another chapter of general nature devoted to the organic composition and classification, the more systematic treatment follows. A good chapter on hydrocarbons presents the more important information on the chemistry and function of hydrocarbons in plants and animals. Part II covers in thirteen chapters the chemistry and metabolism of carbohydrates and the terminology and evaluation of acidity and pH . The structural relations between the different monosaccharides and between the tautomers involved in the action of bases and in mutarotation are not presented clearly. The actions of strong mineral acids on carbohydrates and of bromine on reducing sugars are not adequately covered. It is also rather unusual to discuss the asymmetrical carbon atom after considerable material has been presented which involves its knowledge. The synthesis of carbohydrates in plants, the various fermentations of carbohydrates, and the changes in the digestive tract and blood sugar and its regulation are well presented. The biochemistry of diabetes is given well with the exception of the ketogenic and antiketogenic values of various foods. While the basis of pH terminology is given clearly, the development of the buffer action in tissues and body fluids is given too simply. Part III in three chapters covers lipins. The treatment of phospholipins and cerebroside is very brief. The chemistry of sterols, bile acids and related compounds is treated fairly well but the information on vitamin D and sex hormones is not as critical and complete as one might desire. Curiously Brown-Séquard is the only one referred to in connection with the internal secreting function of the gonads. Part IV, in twelve chapters, covers the chemistry and metabolism of proteins. With the exception of too brief a treatment from the physical-chemical point of view, the discussion on this phase is very satisfactory. Each chapter is preceded by a good summary, and an excellent subject index is provided.

Radium Treatment of Skin Diseases. New Growths. Diseases of the Eyes and Tonsils. By Francis H. Williams, M.D. Senior Physician, Boston City Hospital. Cloth. Price \$2. Pp. 118 with 12 illustrations. Boston: Stratford Company, 1935.

In this book Dr. Williams limits himself in subject matter to those details of radium treatment with which he has had particular personal experience. The opening chapters are devoted to a discussion of some of the physical properties of radium and a detailed description is given of the fluorometer, an instrument devised by the author, with which he was able to measure comparatively the beta ray penetration of radium in water layers of varying thickness. From the measurements obtained he lays down some of the principles that guide him in radium treatment. Approximately the latter two thirds of the book recounts the results of Dr. Williams' experience with radium particularly as applied to a limited group of lesions of

the skin, eye and throat. Descriptions and photographs of instruments developed and used by the author are included with the text, as well as details of the technic of application. In general, it may be said that the author's observations are not only clear and easily understandable but also borne out by the experience of other radium therapists, working elsewhere. The past twenty-five to thirty years has furnished sufficient evidence to corroborate beyond all doubt the truth of the general laws and principles laid down by Dr. Williams. As an approach to the broader subject of radium therapy as now generally practiced the book may prove misleading, in that the action of gamma rays is minimized and most radium therapists are not treating infected tonsils or cataracts with radium at this time. The impression might conceivably be formed by the reader that radium is effective almost entirely as a result of the action of beta rays. This volume will no doubt prove of most interest and value to one already familiar with radium and its use, since its emphasis is on a limited field of radium therapy and development of technic as applied to these particular conditions by Dr. Williams. Generally speaking, the book is of interest and presents the experience, methods and technic of one individual in a limited field. It presents many of the problems that confronted the early workers with radium and the author's methods of solving these problems. The book is interesting reading but gives too little space to the more recent advances in the use of radium to be of much aid in the practice of radium therapy in the more commonly accepted methods and technic today.

Handbook of Bacteriology for Students and Practitioners of Medicine
By Joseph W. Bigger, M.D., Sc.D., F.R.C.P.I., Professor of Bacteriology and Preventive Medicine, University of Dublin. Fourth edition. Cloth. Price \$4.25. Pp. 458 with 93 illustrations. Baltimore: William Wood & Company, 1935.

This book was the outcome of some dissatisfaction with the larger textbooks on bacteriology frequently expressed to the author by medical students. His object in writing a book was therefore to supply accurate information on bacteriology in a form suitable for students. That he has done so is indicated by the fourth edition of his book published in ten years and further by the appearance in 1935 of the first Spanish edition. The author appears to have included in the latest edition all the advances in bacteriology that appear sound and of importance to medical students. By deleting less important material he has kept the book to exactly the same number of pages as the previous edition. There have been added also a number of colored plates and nine new illustrations, two thirds of the pages in this edition have been changed to bring the book down to date, so rapid have been the advances in bacteriology in the three and a half years since the third edition came out. Its handy size is an advantage to students who have many books to carry about.

Experimentelle Untersuchungen über Amöbenruhr. I. Teil. Krankheitsverlauf bei künstlicher und spontaner Übertragung der Amöbiasis. Von Dr. Oskar Wagner. Beihefte zum Archiv für Schiffs- und Tropenhygiene, Pathologie und Therapie exotischer Krankheiten. Band XXXIX. Beiheft 1. Gegründet von C. Meuse. Herausgegeben von P. Mühlens, Direktor des Instituts für Schiffs- u. Tropenkrankheiten, Hamburg. Paper. Price 3 marks. Pp. 48 with 6 illustrations. Leipzig: Johann Ambrosius Barth, 1935.

A human strain of *Endamoeba histolytica* retained its virulence after having been transferred for eight years, intrarectally from kittens to kittens, from kittens to dogs, and vice versa. Similarly, cultures of *Endamoeba histolytica* failed to lose their virulence. In kittens the disease ran a rapid course, with incubation period very short, about two days in the majority of cases, followed by a bloody diarrhea, loss of weight and appetite, and finally death after several days. Ninety per cent of the young kittens died within five days after onset of the symptoms. Older heavier cats were less frequently infected and lived longer. Old heavy cats occasionally recovered spontaneously. Of 1,553 infected cats, forty-three recovered spontaneously. Young kittens never recovered spontaneously. Young puppies (60 per cent from 2 to 3 months old) were more easily infected than old dogs which recovered spontaneously. With the increase in age and size dogs become more resistant to infection with *Endamoeba histolytica* than cats. In dogs the symptoms were much milder and spontaneous recovery much quicker than in cats. Liver abscesses were also less frequent. Occasionally young dogs developed amebic ulcers of the

small intestine and stomach, showing trophozoites in the bloody mucous secretions. Attempts were made to infect rats, monkeys, guinea-pigs and rabbits, but without success. Healthy monkeys as well as rats harbor amebas similar to *Endamoeba histolytica* except that they were unable to produce amebic dysentery in kittens from amebas obtained from these sources. Young puppies became spontaneously infected when exposed in a cage with an infected puppy whose stool showed trophozoites of *Endamoeba histolytica*, but no cysts. Dogs became infected in nature through ingesting human feces containing *Endamoeba histolytica* cysts. By feeding experiments in which only trophozoites of *Endamoeba histolytica* were used, young puppies and kittens became infected. Feeding *Endamoeba histolytica* cysts to a cat and dog resulted, after a long period of incubation (from fifteen to forty-five days), in infection.

Eat, Drink and Be Wary. By F. J. Schlink. Cloth. Price \$2. Pp. 322. New York: Collier, 1935.

This is a typical example of the output of Mr. Schlink as a leader of Consumers' Research. Encouraged, no doubt, by the public reception given to "100,000,000 Guinea Pigs," Mr. Schlink continues to strain at sensationalism in his desire to hold his audience. Unfortunately Mr. Schlink is a chemist by training and not a physician and he is apparently utterly unable to evaluate scientific medical evidence properly. For example, Dr. Eddy in *Good Housekeeping* has told readers that there are no dangers from poisons in modern enamels on cooking ware, Mr. Schlink tells them that Consumers' Research has found poisons in enamels. Of course, the significant fact is not that there are poisons in enamels but whether or not such poisons in enameled cooking ware possess any real potentialities for poisoning those who use the cooking ware. This is the difference between the chemical and the biologic approach. Dr. Eddy in *Good Housekeeping* says that gelatin is a good protein. Mr. Schlink comes forth with the old bugaboo that gelatin is made from hoofs and hides and he insinuates, therefore, that it is not a good protein. Sausage is made from portions of meat that used to be thrown to the fertilizer, yet the Eskimos have proved to us that most of the glands and entrails are valuable in the diet. Liver used to be cat meat and is now more valuable than steak. It would be easily possible to go through this entire book page by page and to point out similar exaggerations and misinterpretations of scientific evidence.

Mr. Schlink continues to quote profusely from *THE JOURNAL* and other American Medical Association publications, in fact the majority of his material comes from these sources yet he does not hesitate to bite the hand that feeds him and to quarrel with some of the official bodies of the American Medical Association on points concerning which he himself is not competent to judge satisfactorily.

For those who are really serious about securing real information on the physiology of foods and digestion, the book by Mr. Schlink cannot be recommended. To those who want their imaginations titillated by muckraking, Mr. Schlink's book will probably be welcome.

International Bibliography on the Problems of Blood Transfusion and the Theory of Blood Groups, 1900-1933. Edited by Dr. E. Koenig and Prof. E. Hesse. [In Russian, German, English, French and Italian.] Paper. Price 12R 50k. Pp. 226. Leningrad: Research Institute of Blood Transfusion, 1935.

This bibliography presents the titles of 4,423 articles on blood transfusion published in the world literature since 1900. Titles of papers published in English, German, French, Italian or Russian are printed in the original language. The Russian publications are printed in Russian and German. Titles of papers from sixteen other countries are printed in German. The enormous material is divided into twenty-two groups and seventy-seven subgroups. For instance the whole literature on blood groups is given on seventy-three pages, with 1,861 titles. Papers on technic and indications are quoted in the same exhaustive manner. No article is reported in more than one section but at the end of every section the corresponding numbers of articles previously referred to are cited. Thus easy access to the world literature is given to anybody who is interested in any phase of blood transfusion. Investigation of the previous publications on the different problems of blood

transfusion can be carried out now in the shortest time, instead of days or weeks spent in looking up the literature. This bibliography is a monumental work. The authors should be congratulated on their brilliant accomplishment. In recent years a great deal of new and original work on blood transfusion has originated in Russia. This book expresses the active interest which our Russian colleagues take in the popularization of blood transfusion.

Medicine for Nurses By W. Gordon Sears, M.D., M.R.C.P., Deputy Medical Superintendent, St. Charles Hospital, London. Cloth, Price \$3.25. Pp. 412 with 46 illustrations. Baltimore: William Wood & Company, 1935.

This is a treatise based on a series of lectures to nurses. The material is written in a compendious style with additions made to emphasize the importance of nursing in the various conditions. Apparently irrelevant material is included to cover the possibility of future examination questions. In several instances the treatment and prophylactic measures detailed are not the most modern. For instance, to avoid in diphtheria is not mentioned, gauze dressing on a vaccinia pustule is advocated, nasal catheter administration of oxygen in pneumonia is described as a method of choice, and active immunization against scarlet fever is omitted. Except for these few shortcomings, the volume is easily readable, covering a large subject well within the grasp of individuals who have not had a sufficient medical education.

Social Problems of the High School Boy By Alba M. Lyster, Chairman, Arts and Sciences, the Vocational and Technical School, San Antonio, Texas, and Gladys T. Hudnall, Chairman, Home Economics, Austin Senior High School, Austin, Texas. Reviewed for educational value by Benjamin Lloyd Pittenger, Ph.D., Dean of the School of Education, The University of Texas, Austin. Cloth, Price \$1.75. Pp. 340 with 71 illustrations. Austin, Texas: Steel Company, 1935.

This book is intended to help the high school boy make his social adjustments. The reviewer and his wife have gone through it more or less carefully expecting to find a whole lot of prissy directions concerning the fine points of etiquette which would be practiced only in the upper brackets of society. They found little or nothing of the sort. Instead here are things that every boy should know. He is given the principles of physical health and something concerning the food he should eat, manners are discussed in considerable detail, the boy is instructed in the principles by which he may choose and wear his clothing, he is given a great many hints as to how to decorate his room. There are many suggestions about the choice of a vacation, he is told how to cook simple foods in case his mother or his wife should be ill, the choice of a mate is sensibly discussed, his relation to other boys and to girls is taken up in a logical and attractive manner. The information in this book will be a tremendous aid in making the transition from high school boy to useful man. Every high school boy and his parents should have a copy of it.

Restauration et prothèse maxillo-faciale. Fractures—pertes de substance—différentes Par les Drs. Ponroy et Psaume, médecins du centre maxillo-faciale de Paris. VIII. La pratique stomatologique, publiée sous la direction du Dr. Chompret. Préface du Professeur Fernand Lemaître. Cloth, Price 30 francs. Pp. 502 with 338 illustrations. Paris: Masson & Cie, 1935.

This is the eighth in a series of nine volumes on the practice of stomatology. It contains a wealth of detail and should prove an excellent reference volume for the dental surgeon primarily. The lower jaw is considered in the first part. Line drawings are used exclusively except for reproductions of two roentgenograms and four photographs of two patients. Infinite detail of dental fixation is given and illustrations of many different ideas of splinting and the application of prostheses. Roentgen examination is covered in less than half a page and no diagnostic reproductions are shown. The only two roentgenographic reproductions in the entire book are of a graft across a defect of the body. The second part covers the upper jaw and has a short treatise on cleft palate. The third part considers the covering of the face and includes illustrations of one nasal reconstruction. Many excellent individual procedures may be found throughout the book with special reference to mechanical features. It might serve the purpose for the general or oral surgeon of giving a better outlook on the dental problems involved otherwise the actual management of jaw fractures may be found more practically explained elsewhere.

Outlines of General Psychopathology By William Malamud, M.D., Professor of Psychiatry, State University of Iowa. Cloth, Price \$5. Pp. 462. New York: W. W. Norton & Company, Inc., 1935.

In this book the author presents systematically a consideration of abnormal mental activity. His presentation is based on actual case reports. In the course of his presentation he outlines the various new conceptions, including behaviorism, Freudianism, individual psychology and similar doctrines. In his presentation he develops a psychologic nomenclature. Whereas his table of contents seems abnormally abstruse and difficult, the book itself is easy to read, direct in its approach, and quite comprehensive. It is the kind of volume that may be cheerfully recommended to the general practitioner who wants to orient himself in a field in which most writers are confusing.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice—Abandonment of Patient, Scope of Experimentation in Medicine—The plaintiff, because of a swelling of his left knee, consulted the physician defendant, who took a history of the case, examined his patient manually, and made a diagnosis of sarcoma. He placed his patient on a diet and one week later gave him "an antitoxin injection." Whether the injection was made into the supposed sarcoma or intravenously, or otherwise, the decision does not disclose. About four days after the injection the skin over the swelling broke open, and a cauliflower mass developed. The defendant dressed the sore with sterile gauze bandages, applied boric acid, and used "pheno isolin,"¹ with morphine to relieve pain. The defendant then—after, the record implies, promising to return—discontinued attendance. The mass of diseased tissue had by that time increased in size and was discharging large quantities of pus, and the plaintiff consulted another physician.

This second physician sent him to a hospital, where roentgenograms were made and a Wassermann test, and where tissue from the diseased area was examined microscopically. Chiefly on the basis of a positive Wassermann test, the lesion at the knee was attributed to syphilis and diagnosed not as a sarcoma but as a gumma. Antisyphilitic treatment was then administered, followed by immediate improvement. The plaintiff returned to work, but he continued to suffer pain and his left leg remained crippled and stiffened. He sued the physician who first treated him, the defendant in this case, claiming that the defendant was negligent in that (1) he failed to exercise the degree of care and skill required of him, (2) he did not use roentgen rays to aid in making a diagnosis, (3) he did not take specimens of tissue for microscope examination, (4) he injected poisons or harmful drugs "into the blood stream," and (5) he abandoned the plaintiff without cause. The jury returned a verdict of \$25,000 in favor of the plaintiff, which the trial court thought excessive, and with the consent of the plaintiff judgment was entered for only \$7,000. The defendant thereupon appealed to the Supreme Court of Michigan.

The physician defendant contended that the admission of mortality tables in evidence in proof of the plaintiff's impaired earning capacity was error, because the plaintiff was in ill health when the physician-defendant was called to attend him and therefore did not belong to that class of persons whose lives form the basis of such tables. The Supreme Court agreed that the admission of mortality tables in evidence under such circumstances was error as the expectancy of life stated in them is based on the lives of healthy individuals, but the court was of the opinion that by the reduction of the verdict from \$25,000 to \$7,000 the error had been cured, since the error affected only the amount of the verdict.

The charge of the trial court that if the physician defendant promised to return to see the plaintiff and never did so, but

¹ A proprietary drug not an antitoxin but shown by analysis to consist essentially of turpentine, camphor, menthol and resin dissolved in oil. Condemned as misbranded under the U. S. Food and Drugs Act. See food inspection decision No. 23230. U. S. Dept. of Agriculture.

abandoned him, and damage resulted from that conduct, and that if such conduct was not in accordance with the usual and ordinary practice of physicians in the community and in similar communities, the physician-defendant was liable, the Supreme Court held was correct. The court concluded "When a physician takes charge of a case and is employed to attend a patient, the relation of physician and patient continues until ended by the mutual consent of the parties, or revoked by dismissal of the physician, or the physician determines that his services are no longer beneficial to the patient and then only upon giving to the patient a reasonable time in which to procure other medical attendance." The question of abandonment in this case was in dispute and was properly left to the jury.

The record shows, said the Supreme Court that when the physician-defendant made the manual examination of the plaintiff, the plaintiff had symptoms that would lead a physician to suspect cancer, syphilis, simple tumor, abscess or tuberculosis. The usual practice among physicians in the community in diagnosing the cause of a swelling such as the one on the plaintiff's knee at the time was not only to take a history of the patient but also to have a roentgenogram made, a blood test made and a microscopic examination of the tissues. A physician is bound to follow the usual and ordinary practice of physicians of ordinary learning, judgment or skill in his own or similar localities. In this case, which was not an emergency case the defendant did not use ordinary diligence in availing himself of various methods of diagnosis for discovering the nature of his patient's ailment, such as were used by physicians of skill and learning in the community in which he practiced, and he must therefore, in the opinion of the Supreme Court be held liable for the damage due to his negligence. The Supreme Court recognized, however, 'that, if the general practice of medicine and surgery is to progress, there must be a certain amount of experimentation carried on but such experiments must be done with the knowledge and consent of the patient or those responsible for him, and must not vary too radically from the accepted method of procedure.'

The physician-defendant requested the trial court to instruct the jury not to consider the charge that the defendant injected a harmful or poisonous drug into the plaintiff's blood stream, because there was no evidence to support such a claim. The trial court, however charged the jury that it was alleged in the declaration that the plaintiff had done so and stated that there was some testimony tending to support the allegation. A search of the record, said the Supreme Court, fails to disclose any evidence that the injection given to plaintiff by the physician-defendant was poisonous or harmful and the trial court should have given the instruction requested by the defendant. The instruction that the court did give erroneously assumed the existence of certain facts and this, with the court's failure to instruct the jury as requested, was prejudicial error. The effect of it on the minds of the jury could not be ascertained and therefore the erroneous instruction was not cured by the diminution of the amount of the verdict. The Supreme Court, therefore, directed that a new trial be given.—*Fortner v Koch (Mich.) 261 N W 762*

Malpractice Statute of Limitations, Concealment of Cause of Action.—The defendant, a physician operated on one of the plaintiffs Sept 2 1931. He employed Dr F F McMillan to administer the anesthetic. During the operation the patient lost a considerable amount of blood, and tight bandages were applied to her legs. Shortly after the operation the defendant left for another city without giving orders for the removal of the bandages. He was absent four days. Dr McMillan the anesthetist too left town, and he was absent until the next day after the operation. When and by whom the bandages were removed is not clear from the report of this case but they were not seasonably removed and the patient developed ulcerated areas on her legs with paralysis substantially complete from the knees down. After his return, Dr McMillan visited the patient a few times responding apparently to a call by the nurse. Later the defendant treated the patient for a time and finally sent her to a hospital.

For nearly a year the patient and her husband corresponded extensively with the defendant looking toward a settlement of their claim for the injuries attributed to his negligent treatment.

Finally, Aug 25, 1932, the defendant agreed to pay them \$3,500 and they agreed not to sue him, and a covenant was entered into between them to that effect. The patient and her husband did, however, sue Dr McMillan. In the first trial a disagreement of the jury resulted and in the second trial the jury returned a verdict in Dr McMillan's favor.

The patient and her husband then instituted action to have the court set aside the covenant into which they had entered with the defendant in this case, by which in consideration of the payment by him of \$3,500, they had agreed to refrain from suing him. They contended that the defendant had practiced fraud on them in obtaining that covenant. He had, they alleged told them that he had expected Dr McMillan to care for the plaintiff on whom he had operated after the operation, that he had made specific arrangements to that effect that such was the local custom, and that he would so testify if they covenanted not to sue him. The defendant had, however, they alleged, at the first trial of their suit against Dr McMillan denied that he had made a specific agreement with him to give postoperative care to the patient. The trial court entered a decree setting aside the covenant and declaring that it was not a bar to proceedings by the patient and her husband against the defendant for negligent malpractice. The defendant thereupon appealed to the Supreme Court of Michigan.

In Michigan actions for malpractice must be instituted within two years from the time the cause of action accrues, but if a physician fraudulently conceals the cause of action, action may be commenced at any time within two years after the person who is entitled to institute action discovers that he has that right. The physician defendant contended apparently, that even if the covenant not to sue should be set aside as the trial court had undertaken to do the statute of limitations had run against the plaintiff's claim for damages arising out of alleged malpractice incident to the operation in 1931. If the plaintiffs said the Supreme Court, knew that they had a cause of action against the defendant the time within which they could institute suit had elapsed. The plaintiffs agreed not to sue the defendant and entered into a covenant to that effect after long negotiations consultations with counsel and threats of a suit. It would be incongruous said the court, to permit a person to plead that the running of the statute of limitations had been stopped by the fraudulent concealment from him of the very same cause of action for which he had accepted a substantial sum in settlement.

The Supreme Court set aside the decree of the trial court declaring the covenant void and reversed the action of that court.—*Hast & Duffie (Mich.) 262 N W 401*

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Effect of Calcium Injections on the Human Heart. K. Berliner. New York—p. 117.

Use of Iron in Experimental Anemia.—The thesis of Whipple and Robscheit Robbins relative to iron utilization in the standardized anemic dog is as follows: Iron given intravenously to a normal anemic dog will be utilized to form new hemoglobin practically on a quantitative basis. 10 mg. of iron equals 3 Gm. of hemoglobin. Therefore in the same dog under certain conditions the amount of absorbed iron may be estimated from the amount of new-formed hemoglobin. In the emergency due to anemia the healthy dog will utilize quantitatively the iron as it comes into the circulation just as under similar circumstances it utilizes quantitatively hemoglobin given intravenously to rebuild new hemoglobin for red cells. Assuming that under these conditions new-formed hemoglobin is a reasonably accurate measure of iron absorbed from the intestine, the ratio of iron ingestion may be calculated to new hemoglobin production. For the optimal dose of iron (40 mg. daily) this ratio will be about 3:1 or a 35 per cent utilization of ingested iron. For larger doses of iron (400 mg. daily) this ratio will be about 20:1 or a 5.3 per cent utilization of the iron given by mouth. This is to be compared with the 10:1 ratio for the feeding of whole blood cells by mouth for 10 Gm. of hemoglobin fed there is a return of only 1 Gm. of new hemoglobin in the standard dog. The figures of standard salmon bread feeding show that the salmon bread iron gives a 40 per cent utilization of this iron. On the average liver feedings show that the dog utilizes about 44 per cent of the iron contained in normal pig liver in the production of the new-formed hemoglobin. There are many organic and inorganic factors as well as iron that influence hemoglobin production in anemia and any dogmatic generalizations about food iron are not safe. Infection and intoxication will modify internal metabolism and limit the output of hemoglobin in anemia. Bile secretion will also modify the production of hemoglobin in this type of anemia. Eck fistula and splenectomy may modify reactions to iron given intravenously. When iron is given intravenously a quantitative return is observed even when enormous doses are given and the body finds the needed building material to supply the globin—a protein making up about 95 per cent

of the hemoglobin molecule. When an anemic dog is fasted and given iron intravenously, he will form large amounts of hemoglobin, and much of it must come from body protein stores. A considerable part of this new hemoglobin is formed by conservation of material which under control fasting conditions would be wasted as urea in the urine. Amino acids or organ fractions almost free of iron will cause increased hemoglobin production in the anemic dog. Now the dog must draw iron from depleted stores or utilize the food iron even more completely. The authors found it possible to reach the end of the iron stored in the body and observe a fall in hemoglobin production under such conditions but the iron conservation within the body must be truly remarkable.

Iron Metabolism.—Hahn and Whipple observed that reserve iron storage in the dog can be exhausted during a period of from two to three months by a continuous anemia with the hemoglobin level maintained at from one half to one third of normal. A rapid turnover of iron is the conspicuous feature of the experiments dealing with iron given by mouth, and short feeding experiments (one to two days) give no evidence of any iron store in the liver. As the iron feeding experiments are lengthened a variable accumulation of iron in the liver is seen but the amounts are small and a very rapid appearance of the iron in matured hemoglobin is the conspicuous feature. Parenchymal iron of various blood free organs is relatively a constant in the standardized dogs. Liver, kidney and pancreas average from 1 to 2 mg. of iron per hundred grams of fresh tissue; the lung 3 mg., the spleen from 5 to 6 mg., the red marrow probably in excess of 10 mg. and the striated muscles 31 mg., of which about 16 mg. is muscle hemoglobin iron, leaving the parenchymal iron as 15 mg. Muscle hemoglobin iron and muscle parenchymal iron are inviolate stores of iron which are not drawn on no matter how great is the emergency due to anemia. Conversely no surplus iron can be demonstrated in this tissue when iron is given intravenously. Iron depletion can be carried to a point at which there is almost a complete cessation of hemoglobin production in a standard dog on a diet poor in iron. Intravenous iron in the doses given will result in large storage in the liver and spleen from 55 to 70 per cent of the total iron given. The authors are not prepared to say where the remaining iron is to be located in the body tissues or fluids, but it certainly is not eliminated.

The After-History of Lipoid Nephrosis.—Major discusses the after-history of lipoid nephrosis in six patients, one of whom has been followed for eight years, two for four years and one for three years. Two of the patients died showing marked acute glomerular nephritis with evidence of chronic glomerular changes at necropsy. Of the four patients living three are clinically well and one appears in good health and still shows a definite but not constant albuminuria. The three patients who have apparently recovered have been under observation eight years, four and one half years and four years. The patient who has recovered except for the slight albuminuria has been under observation three years. At one time or other practically every method of treatment recommended has been employed including high protein diets, blood transfusions, intravenous dextrose, thyroid extract, parathyroid extract and various diuretics including merbaphen and salyrgan. The authors have given their patients from 70 to 100 Gm. of protein daily. Very high protein diets in their experience present a difficult problem. Studies of the nitrogen balance in two patients also indicated that an excess of protein intake was not stored but excreted as urinary nitrogen. Blood transfusions and intravenous injections of solution of dextrose were apparently of temporary value at least. They have not found thyroid extract or parathyroid extract of any definite value. Bacterial antigens were of questionable value. They have seen no detrimental effects from the use of merbaphen or salyrgan. At times they produce abundant diuresis and at other times no apparent effect. One patient was given intravenous acaeri and a few days later developed an acute nephritis with death. This may have been a coincidence. The last three patients have been placed on a high carbohydrate diet of from 600 to 800 Gm. daily occasionally as high as 1000 Gm. They have improved remarkably either as a result of the diet or because of the healing powers of nature.

Effect of Calcium Injections on the Heart—Berliner found that the intravenous injection of 10 cc of a 20 per cent solution of calcium gluconate produced changes in the electrocardiograms of twenty-six normal individuals. These changes consisted of flattening or inversion of the T waves in 92 per cent of the cases, flattening or inversion of the P waves in 44 per cent and a marked bradycardia in 67 per cent. Intravenous injection of 10 cc of physiologic solution of sodium chloride given to eighteen normal individuals had no effect on the electrocardiograms. This investigation, for the first time, supplies experimental proof of the effect of calcium on the normal human heart.

Lower Lung Line—Korol points out that in roentgenograms of the upper part of the abdomen there may be seen a horizontal line running from the lateral chest wall toward the first lumbar vertebra on each side. This line (the lower lung line) represents the lower posterior pleural boundary, i.e., the fold of parietal pleura reflected from the posterior chest wall onto the diaphragm. This line may be followed into its junction with the line representing the posterior mediastinal pleural fold. Occasionally the lower anterior pleural fold may also appear as a horizontal line at a slightly higher level than the posterior lung line. The anterior line has been seen only in cases of emphysema; it can be traced on the roentgenogram into the pericardiopleural fold. In cases of emphysema and visceroptosis, also in cases of pneumothorax, the lower lung lines often appear in the chest roentgenograms as horizontal lines crossing the twelfth rib a short distance below the dome of the diaphragm, which is flattened and placed low in these cases. In cases of atelectasis or fibrosis of one lobe with compensatory emphysema of the healthy lobes, the lower lung line often shows on the routine chest roentgenogram, owing to ballooning of the pleural fold by the emphysematous lung.

Preoperative Radium Treatment of Rectal Carcinoma

—At present Bowring and Fricke employ an aggressive preoperative treatment for rectal carcinoma. Platinum-filtered needles (1 mg) are evenly placed throughout small growths for forty-eight hours, or gold radon seeds are implanted. Contact treatment has also been employed: two or three radon tubes (with 1 mm of brass 0.5 mm of silver and 1 mm of rubber as filters) are strapped side by side with adhesive tape to form a plaque. The tubes are placed through the proctoscope against the growth after the normal wall of the intestine has been packed away with gauze soaked in metaphen; a dose of from 60 to 100 mg hours per square centimeter of malignant tissue is employed. This treatment is repeated daily to different areas of the growth until the entire lesion has been covered. Surgical diathermy is used to reduce the bulk of the medullary tumors and to facilitate the puncture method of radium therapy. From 1930 to 1933 inclusive, fifty-eight

patients were selected for this form of treatment. The full plan of treatment (that is, radical excision following radium therapy after an interval) was carried out in only thirty-seven cases. Thirty-one of the patients are living at the present time, although two are seriously ill and two others may have residual trouble. The remaining twenty-seven patients appear to be well and free from recurrence. In five of these, complete healing of the posterior wound has not yet occurred. Six patients have been perfectly well for more than four years. Careful microscopic examination of removed tissue was carried out in all cases following surgical excision of the growth. In three cases no evidence of carcinoma was found in the surgical specimen, radium treatment apparently having destroyed all vestiges of the growth. In three other cases the pathologist found that most of the malignant cells had been eradicated by radium.

Roentgen Therapy of Thrombo-Angitis Obliterans—Pfahler uses 200 kilovolts and 0.5 mm of copper filtration in the radiation treatment of thrombo-angitis obliterans. Since the sympathetic ganglions are approximately from 10 to 12 cm from the surface of the skin, it seems more logical to use a higher voltage and higher filtration technic. The surface dose will vary therefore with the quality of rays used. He advises from 20 to 30 per cent (150 to 200 roentgens) of an erythema dose at each session. The distance has been usually from 40 to 50 cm. The area usually treated has involved the paravertebral region from the eleventh dorsal to the fifth lumbar vertebra. In some cases this has been divided into four portals and the treatment through each area is given on separate days or through two areas on each of two days. The larger the area used, the more likely is radiation sickness to occur. From a review of the cases treated, it would seem advisable to treat the patient over the sympathetic ganglions indicated by the location of the disease probably three times a week until a total of one-half to a full erythema dose has been given over each portal or over the whole area. Such a series may be repeated after an interval of one or two months if necessary. Pain is relieved usually in about two to three weeks after the inception of the treatment, and at times it occurs more promptly. One of the author's patients could walk only a city block, when he would have to stop because of pains in the calf of the legs. He has been completely relieved and three years later can play thirty-six holes of golf at the age of 67. Usually patients have returned to their work in from five to six weeks. The relief of special symptoms has been somewhat as follows: Intermittent claudication disappears sufficiently within two weeks for the patient to walk without distress, and in 50 per cent of the cases reported by Philips and Tumick these symptoms disappeared completely within six weeks. Circulatory and trophic disturbances improve in from four to six weeks. Ulcerations show a tendency to improve within a few weeks and disappear within a few months. Granulations appear and epithelization of the margins is noticed early and an appearance of an ordinary ulcer is soon established. A tendency for gangrene to become dry was noticed early and gradually the dead tissue separated and the area healed. Marked general improvement appears rapidly, chiefly owing to the relief of pain.

Subtemporal and Suboccipital Myoplastic Craniotomy—Cone and Penfield outline a simple technic, myoplastic subtemporal craniotomy, which permits rapid exploration through a wide unobstructed opening and provides a firm, safe restoration. A curved incision is made in the scalp without wounding the pericranium. This incision starts the superior temporal line to which the fascia of the temporal muscle is attached. Posteriorly the incision is swung slightly forward on the supramastoid crest. The superior temporal line is identified anteriorly by palpation. As this incision is deepened, the pericranium is exposed just beyond the temporal muscle fascia. By palpation the extent of the temporal muscle fan can be outlined quickly by having the patient bite. The scalp flap is reflected from the periosteum until the temporal fascia attached to the superior temporal line of the parietal bone and the posterior part of the temporal ridge of the frontal bone is exposed. An incision is carried down to the calvarium through the line of fascial attachment and the muscle and scalp flap are reflected from the temporal bone and retracted with two or three guy sutures attached to rubber bands. The bone is removed from the temporal fossa up to within a centimeter or less below the fascial incision. An opening from 9 to 7 cm is thus readily obtained. To reattach the myoplastic flap, holes are made in the margins of the bone defect, usually from twelve to fourteen, and interrupted chromium steel wire sutures, size 33, are passed through the holes and up through the muscle and overlying fascia and are tied next to the bone. The fringe of fascia and pericranium left attached to the flap as it was reflected is sutured either with interrupted silk sutures or with a continuous locked silk suture, and the scalp is closed in two layers, as usual. In myoplastic suboccipital craniotomy used for bilateral or unilateral exploration of the posterior fossa the incision extends from the level of the tips of the mastoid processes to a point from 4 to 5 cm above the external occipital protuberance. The lateral wings of the incision are so placed that the muscles of the neck attached to the mastoid process will not be cut, the incision coming down through the occipitalis muscle directly to the periosteum of the mastoid bone. The incision in the scalp includes the galea but not the pericranium. The upper concave edge of the incision may be separated from the pericranium in an upward direction to allow the bur holes to be made for ventricular puncture. The scalp flap is reflected downward as far as the external occipital protuberance. The pericranium is then incised and while the flap is being retracted the suboccipital muscles are elevated from the bone down to the foramen magnum. The whole flap is held out of the way with guy sutures attached to rubber bands. Removal of the bone is carried down to the foramen magnum and upward so as to expose the transverse sinus as desired. Removal of the bone has been frequently carried high enough to permit ligation of the sinus section of the tentorium and elevation of the occipital lobe. At closure in order to reattach the reflected myoplastic flap from fourteen to sixteen holes are made in the margin of the bone defect about 1 cm apart. Babcock's rustless steel sutures are passed through the holes through the

muscle and its aponeurosis, and then tied next to the bone. The fringe of pericranium left attached to the flap is then sutured, and the scalp is closed in two layers as usual. Silk is used for the buried sutures. When drainage is instituted, rubber dam tubing of small size is carried out through a separate stab wound at some distance above the incision. The long tract makes it possible to stop drainage of cerebrospinal fluid at once by pressure when the drain is removed.

Injection into Gasserian Ganglion—Putnam and Hampton describe a modification of Hartel's method of injection into the gasserian ganglion in which the puncture is made during a brief period of anesthesia and the position of the needle is established by means of roentgenograms taken during the procedure. This has been carried out in eighteen cases of trigeminal neuralgia, four cases of carcinoma of the mouth and one case of postherpetic neuralgia, with relief in all but one case. Of three patients with migraine one was satisfactorily relieved, another was improved and a third was unaffected. The method appears to have certain advantages over operative section of the posterior root and also over the older methods of injection.

Rôle of Ileocecal Sphincter—Sperling shows that the ileocecal sphincter is competent to withstand pressures of from 10 to 50 cm of water, which conceivably might occur in the course of obstruction of the large intestine. A competent ileocecal sphincter at once converts a simple type of obstruction into a closed loop with all the inherent dangers of strangulation due to increased intra-enteric pressure. Experimentally the effect of such sustained pressures is shown by the development of areas of hemorrhagic necrosis in the colon of dogs. Similar changes occur in the human colon. The term "ileocecal valve" is a misnomer, the organ is more rightly called the ileocecal sphincter. It is subject to definite nervous control, and its competence depends on the tonicity of the fibers of the sphincter. That the tone of the sphincter is increased by stimulation of the sympathetic nerves is confirmed by experiments. Also it is shown that stimulation of the distal part of the colon increased the resistance of the sphincter to back pressure to approximately three times that of the normal sphincter. It is conceivable that the resistance of the ileocecal sphincter to back pressure is greatly increased in cases of intrinsic pathologic conditions of the colon. Stimulation of the distal portion of the colon, acting through Auerbach's plexus, increases the tone of the ileocecal sphincter, making it more competent. Several important clinical observations present themselves with relation to a competent ileocecal sphincter in cases of obstruction of the large intestine. Vomiting is a late symptom in such cases. The competent ileocecal valve allows material to pass into the colon but none to be regurgitated into the small intestine and stomach. Pain, distention and obstipation may be present for several days before the onset of vomiting. Vomiting may then be due to reflexes set up by distention of the colon. In the cases cited, aspiration of the stomach resulted in the return of only a few cubic centimeters, in spite of the fact that these cases represented late stages of obstruction. Nasal suction as a method of decompression is of little value in the treatment of acute obstruction of the large intestine with considerable distention. A single roentgenogram of the abdomen of a patient with clinical intestinal obstruction should

differentiate between obstruction of the small intestine and that of the large intestine. Roentgenography is the only accurate method of determining the degree of distention and the segment of intestine involved. All acute obstructions of the large intestine exhibiting considerable distention should be treated as obstructions of the closed loop type with potential strangulation, by means of operative decompression (cecostomy). Simple mechanical obstruction of the small intestine has been treated successfully at the University Hospital by decompression by means of nasal suction (Wangensteen). Patients who present only partial or low grade obstruction of the colon can be prepared for operation by medical management, and further distention of the colon can be prevented by the use of siphonage by nasal suction.

March Foot with Changes in Bones—Maseritz discusses the subject of march foot, concluding that it is a complication of the "strained foot," characterized usually by a sudden onset of pain and swelling on the dorsal and, to some degree, on the plantar aspect of the middle part and forepart of the foot. Clinically there is a tenderness over the shafts of one or more metatarsal bones and commonly at the junction of the middle and distal thirds of the second and third metatarsal bones rarely over the first or fifth. A roentgenogram when taken immediately, frequently reveals no change but may present a fracture. Periostitis with or without fracture, is often encountered at an early date, but then, in all likelihood, the callus is of longer duration unless the early shadow as Runstrom mentioned, is that of a subperiosteal hemorrhage. Periosteal changes are more commonly seen after ten days and fractures some weeks later. The latter, though, do not always make their appearance. Also periosteal thickening on one or the other side of the shaft is often found associated with march foot. The etiology is still debatable. Periostitis and fracture are positive observations but can be considered only as the end results of march foot. A case is cited presenting the usual changes in addition to (1) fragmentation of the internal cuneiform bone, (2) fracture of the head of a metatarsal bone and (3) fracture of the base of a metatarsal bone. These changes emphasize the possibility that fragility of bone may play an important part in the fractures of march foot. These changes partly substantiate the etiologic theories of some observers and deny those of others, and one may conclude that more serious thought and consideration should be given to the possibility of calcium disturbances in the bone proper.

New Species of Genus *Listerella* from Human Sources

—Burn states that during 1933 and 1934 four persons died at the New Haven Hospital from an infection caused by an unusual organism in which sepsis, focal necrosis of the liver

and meningitis were the predominant features. The organism is described as a small non-spore forming gram positive bacillus that has a tendency to form short chains and small clumps in broth. A clear beta zone of hemolysis is produced in blood agar plates. Hemolysis of blood in meat infusion broth also occurs in twenty-four hours at 37 C. Cultural and morphologic characteristics indicate that this organism is probably a new species of the genus *Listerella*. Specific agglutinin and absorption tests show that the four strains of this new pathogen are identical. It is pathogenic for rabbits, guinea-pigs, mice, monkeys and man. Lesions produced by the organism consist primarily of a focal necrotizing process and exudation, which are most marked in the liver. Localization of the organism in the central nervous system of rabbits and monkeys results when it is inoculated into the venous blood system. Intravenous inoculations into guinea-pigs cause multiple myocardial abscesses instead of meningitis. Intracerebral inoculations of minute quantities of this organism directly into the subarachnoid space invariably produce an extensive suppurative meningitis in rabbits, guinea-pigs, mice and monkeys. Intraperitoneal inoculations into guinea-pigs cause localization of the organism in the central nervous system without evidence of myocardial involvement. This route of inoculation for rabbits and mice proves fatal in forty-eight hours if optimal dosages are employed. Macacus rhesus monkeys show a remarkable degree of resistance surviving the infection even after it has once become established within the central nervous system.

Inhibition of Schwartzman Phenomenon—Ogata confines his discussion to a series of experiments concerning the inhibition of the Schwartzman phenomenon by means of active bacterial filtrates and he finds that the phenomenon can be inhibited if an additional intravenous injection of a potent bacterial filtrate is given within one hour prior to or following the skin preparatory injection. The inhibitory effect of the additional intravenous injection takes place within the limits of certain quantitative relationships. Thus if the skin is prepared with a large amount of filtrate, the inhibition is absent or incomplete. Similarly if a large amount of filtrate is used for the provocative injection there occurs no inhibition. The inhibition described is of a transitory nature. The additional intravenous injection given several hours before or after the skin preparation has no inhibitory effect. The inhibition can be obtained only with filtrates capable of eliciting the Schwartzman phenomenon. Bacterial filtrates of low reacting potency as well as nonbacterial substances produce no inhibition. The mechanism of the inhibition remains unknown. The inhibition of the Schwartzman phenomenon cannot be interpreted as an anaphylactic desensitization for the following reasons: 1. Inhibition takes place if the additional intravenous injection is given simultaneously or shortly before and after the preparatory injection. Obviously an anaphylactic desensitization cannot be expected to occur before sensitization is induced. 2. There is no specificity of inhibition. A great deal of experimental evidence in the literature supports the possibility that processes exemplified by the Schwartzman phenomenon take place in induced and spontaneous bacterial and virus infections. The factors responsible for the Schwartzman phenomenon and derived from infected foci may induce a state of reactivity in tissues and organs removed from the sites of initial infection. When the state of reactivity establishes itself, discharge of the same factors into the blood stream would then elicit severe hemor-

rhagic lesions in these reactive sites. The mechanism might then be responsible for pathologic lesions scattered throughout the body, and the inhibitory reaction described in this paper might prevent their occurrence.

Psychiatric Aspects of Myxedema—Akelaitis declares that in every case of myxedema not complicated by a psychosis there is a specific mental condition characterized essentially by psychomotor retardation and fatigability. Since the patients appreciate their difficulties they are apt to be depressed and irritable. This is dependent on the degree of myxedema and the individual. Stuporous conditions may occur in myxedema as illustrated by one of his cases. There is no specific type of psychosis associated with myxedema. The most frequent type of disturbance is a dysergastic (delirious hallucinatory) reaction characterized by a clouding of consciousness which may progress to complete disorientation, vivid hallucinations that are not primarily complex determined, unsystematized delusions of persecution and excitability. Myxedema may precipitate a psychosis in an individual with latent psychotic tendencies. In such a case the type of psychosis may be determined by the prepsychotic personality as seen in another of the author's cases. Definite improvement occurs under treatment with thyroid, and the treatment should be individual in each case of myxedema. It is advisable to start with small doses of thyroid, because these patients are extremely sensitive to the extract.

Hyperpyrexia in Treatment of Syphilis—Dennie and his associates assert that efficient temperatures can be produced in syphilitic patients by the use of the hot bath. They believe

that in some way the defense mechanism of the body is raised and the virility of the organism lowered simultaneously by the use of hyperpyrexia. Experimental work seems to show that temperatures of 104 F and higher set the defense mechanism in motion. In the cases presented it was not necessary to keep the temperatures at this level for long periods (ten minutes). With the exception of early seronegative syphilis inadequately treated syphilis with recurrent manifestations and early malignant syphilis, heat should not be used in the early types of syphilis. Heat is best applied in the later forms of syphilis, no matter what the manifestations. The provocative Wassermann effect was produced in 20 per cent of the seronegative cases. By the application of heat alone it has been shown that syphilitic manifestations disappear temporarily, if subsequent treatment with heavy metals is employed, they disappear permanently. Heat is an efficient therapeutic agent in recurrent neurosyphilis when malaria has already been used; the manifestations in the somatic system disappear with promptness. The authors predict that heat as an adjunct to the treatment of latent syphilis will become an integral part of the adequate treatment of syphilis. Malaria still remains supreme as the treatment of neurosyphilis. Heat as a therapeutic agent is probably the equal of malaria when used in other than neurosyphilis. The work presented is experimental and is not presented with the idea that all the statements are absolutely proved. They have shown that any form of hyperpyrexia enhances subsequent treatment.

*Practical Limitations of Vaccine and Serum Therapy A B Wadsworth Albany N Y—p 1285
Progress in Study of Cardiovascular Disease in 1934 S McGinn Boston—p 1293

Limitations of Vaccine and Serum Therapy—Wadsworth points out that vaccine therapy is of great use in the prevention of infection by developing an immunity before infection has taken place, whereas serum therapy is limited to the treatment of infection. Immunization with vaccines requires time for the active immunity to develop and thus varies greatly with the different vaccines. Nevertheless vaccines are useful under certain conditions and in certain types of infection, which may be defined as the prolonged infections of low grade in which the disease process is not developing an adequate immunity and requires the further stimulation that might be derived

from judicious treatment with a potent vaccine. Immunity to bacterial infection can be and is obtained by immunization with dead bacterial cells or their toxins, whereas it is extremely doubtful whether an effective immunity against the virus diseases can be obtained without the introduction of the living virus and the development of some form of disease process in the tissues. Dead bacterial material may induce an extremely high degree of immunity which subsides and becomes latent when immunization has stopped, just as it does after the recovery of a person from bacterial infection. After recovery from the virus diseases, a second infection is extremely rare. The immunity is lasting, practically permanent for the duration of life. Similarly after the administration of a living virus in a vaccine the immunity is likely to be lasting with extremely rare exceptions—as for example, in the case of smallpox that develops in a person who has been vaccinated. Serum therapy is passive immunization in contrast to active immunization—vaccine therapy. Progress in the development of serum therapy, as in preventive immunization, has been hampered by obsessions regarding the specificity of the different hemolytic streptococci with relation to a particular disease. The strains differ and within certain limitations, can be classified but the author's studies of 1,500 cultures from all sources has established the fact that the same strains are found in scarlet fever as in septic sore throat or erysipelas, and they occur in about the same percentages in each disease. There is as yet no definition of a hemolytic streptococcus specific to scarlet fever, septic sore throat erysipelas or any other streptococcal infection. Attempts are now being made to improve and broaden the therapeutic action of the serums. The difficulty has been that, in the attempt to broaden the valence, the potency has been sacrificed. Serum therapy in streptococcal infection is further complicated by the fact that there are certain differences in the action of antitoxic and antibacterial serums not as yet fully understood. Conflicting opinion regarding the practical value of antimeningococcus, antipneumococcus and anti streptococcus serums in the treatment of infection during the past twenty years is to be attributed to the variation in the potency of the serums that have been available for treatment.

Surgical Treatment of Corns—Galland states that the ordinary clavus is amenable to operative treatment. The operation must eliminate the factors that produce the recurrence of the clavus—the hyperkeratosis the bursa and the juxta-articular prominences. The operation is simple and devoid of any great risk of complications. He has performed it during the last four years without any complicating incident. No infections have been encountered and without exception these patients have been able to walk around with a fair degree of comfort within four days after operation. Several interns and nurses operated on for corns have continued their duties without interruption following this procedure.

Changes in Ureter Associated with Pregnancy—Traut and McLane state that the normal ureter of the nonpregnant woman is possessed of rhythmic peristaltic activity which can be measured and recorded. This rhythmic peristaltic activity was definitely altered by pregnancy in varying degrees in the majority of the thirty four patients studied. This altered peristaltic activity is expressed by diminished amplitude of the peristaltic wave commencing in the third month of pregnancy but reaching its peak during the seventh and eighth months. After the fifth month the number of patients showing diminished ureteral response exceeds those showing normal activity. During the last month of pregnancy there seems to be a definite return of muscular irritability as expressed by the measurement of peristalsis and response to stimulation. This diminished peristaltic activity of the ureters seen in pregnancy cannot be explained on a basis of dilatation. On the contrary dilatation of the ureters during pregnancy is probably in great part dependent on the atony of the ureters. The etiology of this observed ureteral atony during pregnancy is in the authors' opinion not dependent on any mechanical factor but rather on some as yet unexplained chemical basis.

Chronic Cervicitis and Infection of Urinary Tract—Herrold and his associates mention that coagulation of the cervix for chronic cervicitis gave satisfactory relief of symptoms referable to the urinary tract in approximately two thirds of their thirty two patients. As yet their investigation has not proved the exact mechanics of such improvement. They favor the view that constant reinfection of the urethra and bladder particularly with enterococci, is an important contributing factor. In many instances clinical improvement has been coincident with a decrease of the bacterial flora of the urinary tract. On the other hand some patients with improvement have continued to yield enterococci from cultures of the urinary sediment. It is possible that such remaining infection is more superficial

than before cervical coagulation and would disappear spontaneously or by treatment after a longer period had elapsed. One arthritic patient was relieved of all symptoms within four weeks after coagulation of the cervix. There were two patients who had symptoms similar to a group that is frequently described as idiopathic fever. A diagnosis of tuberculosis had been made in these patients and one had been sent to a sanatorium in New Mexico, where it was decided after several weeks of observation that she was not tuberculous. After coagulation of the cervix the patient's temperature returned to normal and the urine cultures no longer yielded streptococci. The other patient continued to have fever after coagulation but streptococci persisted in the urine cultures and it is possible that the infected gland bearing tissue was not all destroyed. In instances of this sort the Sturmdorf operation would seem to be preferable. One patient who had an early interstitial cystitis received definite improvement following coagulation of the cervix.

Changes in Nervous System in Diabetes Mellitus—Sheppe believes that it is safe to say that advanced degrees of diabetic neuropathy are represented by degeneration of fibers in the dorsal and lateral columns and anterior horns of the spinal cord marked degeneration of the nerve roots and extensive demyelination of the peripheral nerve fibers. The changes frequently produced in the nervous system by the action, direct or indirect, of diabetes mellitus bring on a wide variety of neurologic manifestations involving the higher functions of the cerebrum and the cranial nerves, either singly or in various combinations. In addition to these miscellaneous manifestations, the author has cited five cases with one necropsy to illustrate the syndrome which is produced by diabetes and which markedly duplicates in every way the manifestations of tabes dorsalis. This syndrome is characterized by progressive weakness and paralysis of the lower extremities and either partial or complete paralysis of the bladder. Before making such a diagnosis it is necessary of course to establish the presence of diabetes and to eliminate other diseases that might produce similar effects on the spinal cord (syphilis, pernicious anemia, cord tumor arthritis of the spine and trauma). Diagnosticians should bear in mind the probability of the production of lesions of the central nervous system by a manifest or latent diabetes. The histologic studies and the clinical manifestations of the author's case showed that the changes encompassed by the term 'diabetic neuropathy' are not confined to the peripheral nerves but occur in various portions of the cord as well. These changes consist principally of degeneration of fibers of the cord and nerve roots, followed by moderate gliosis of the cord and marked demyelination in the peripheral nerves.

Vitamins A and D in Cooked and Fresh Foods—Coward and Morgan estimated the vitamin A potencies of milk, butter, egg yolk and various vegetables quantitatively in terms of the international unit by comparison with one sample of cod liver oil of known potency, a test on the oil being made simultaneously with the test on each food substance. The boiling of the vegetables in a manner similar to that used in ordinary cooking did not destroy any vitamin A. Boiled carrots, cabbage and runner beans have been shown to be valuable sources of vitamin A, in view of the amount that can readily be eaten. Their potencies are about one third, one seventh and one tenth respectively of an average sample of summer butter, which contains 60 units per gram. Tables are given showing the vitamin A and D potencies of various foods expressed as the number of international units per gram of food and also as the number of units in a 'portion' of the food usually eaten.

Treatment of Hematemesis and Melena with Food—Meulengracht treated 251 cases of hematemesis and melena arising from ulcer of the stomach and duodenum by giving the patients varied food from the very first day, and plenty of it. From the day after their admission to the hospital all the patients are given a full puree diet, together with a mixture consisting of 15 Gm of sodium bicarbonate, 15 Gm of magnesium subcarbonate 2 grains (0.13 Gm) of extract of hyoscyamine (one teaspoonful three times daily), and one-half gram (0.032 Gm) of iron lactate three times a day. The puree diet includes the following meals: tea, white bread and butter at 6 a.m., oatmeal with milk, white bread and butter at 9 a.m., dinner at 1 p.m., cocoa at 3 p.m., and white bread and butter, sliced meats, cheese and tea at 6 p.m. The dinner includes a variety of dishes, e.g., meat balls, timbale, broiled chops, omelette, fish balls, vegetable gratin, meat gratin, fish gratin, mashed potatoes, vegetable purees, vegetable soups, cream of vegetables, stewed apricots, apple sauce, gruel, and rice and tapioca puddings. The patients are allowed to have as much as they want. In a few cases (twelve) in which large quantities of blood have been lost they have been given one or two blood transfusions soon after admission. Among these 251 patients there were three deaths after the hemorrhage. The

first patient did not die of hemorrhage but of perforation with diffuse peritonitis. The second patient died seventeen days after the commencement of the treatment from profuse hemorrhage from an eroded artery. The third died shortly after admission without having got as far as the "treatment with food." The author believes that this radical change in mortality brought about by treatment with food is due to something beyond its effect on the hemorrhage itself. In his experience patients with hematemesis and melena do not usually die until some time—on an average eight days—after the hemorrhage begins. Thus in his opinion they do not die directly from loss of blood but rather from general exhaustion, often with complications. This exhaustion is no doubt primarily the result of their anemic condition, but it is accentuated by extreme insufficiency in food and drink with which they are ordinarily supplied at this critical moment. With treatment with food, instead of weakening the patient still more he is given support when he needs it badly. From the present knowledge of vitamins and the principles of nutrition it seems justifiable to assume that the healing processes are not favored by an insufficient diet.

Diseases of Thyroid in Children—Cockayne discusses the clinical features, differential diagnosis and treatment of sporadic cretinism, epidemic cretinism, hypothyroidism, juvenile myxedema, thyrototoxicosis, simple goiter and goiter of puberty. The most important diseases of the thyroid in children are those in which its secretion is absent, deficient or excessive. Simple goiter in some families that the author has seen is inherited as a mendelian dominant. Like most hereditary conditions it may affect a single member of a family, making the diagnosis less obvious. Apart from a general enlargement of the gland there are no signs or symptoms of hypothyroidism or of thyrototoxicosis and no ill effects are felt in later life. He believes that no treatment is required. Goiter of puberty is not uncommon especially in girls, and though it is symptomless, it indicates that the thyroid is unable to maintain an adequate secretion without hypertrophy. Small doses of potassium iodide or tincture of iodine are advisable, and iodine ointment may be rubbed into the skin over the gland. As puberty becomes established the enlargement of the thyroid often disappears, but careful watch should be kept for any signs or symptoms of thyrototoxicosis, and, if they appear, suitable treatment should be begun without delay.

Diphtheria Immunization—Bousfield believes that a decision on the following questions regarding diphtheria immunization is of national importance. 1. What antigens are of sufficiently proved value and general suitability for them to be employed by public health authorities and recommended to the profession for use in general practice? 2. What procedure, or alternative procedures should be advocated as routine for the country as a whole? 3. What is to be the agreed announcement to the populace as the legitimate claim for immunization conducted on the lines of the answers to questions 1 and 2? The whole matter is at present handled far too loosely, and these points should not be decided by individual local authorities. Two families, residing in neighboring streets are at present liable to acquire quite different ideas as to the value of immunization when they happen to live in adjoining areas with different health officers. The merits of immunization are sufficient for them to be announced from the house-tops without making any exaggerated or misleading claims.

S Wave of Electrocardiogram I Pines—p 727

Pulmonary Embolism and Coronary Thrombosis—Van Bogaert and Scherer discuss the difficulties sometimes encountered in differentiating between pulmonary embolism and coronary thrombosis. They cite a case in which, three days after an operation for suppurative arthritis of the left knee, a sudden, unexpected cardiovascular collapse occurred. The age (62 years), the gallop rhythm, the electrocardiographic changes and the vascular collapse caused diagnostic difficulty. Death occurred nine days after the accident as a result of terminal dyspnea. Necropsy showed an obstructive embolus of the trunk of the pulmonary artery, which was the immediate cause of death. There was also a mesenteritis of the pulmonary artery and its principal branches. There was a femoral and left hypogastric phlebitis with ectasia of the vesicular veins. No changes existed in the coronaries myocardium or pericardium, but there was considerable dilatation of the right side of the heart. There were numerous small infarcts in the kidneys. The major question raised is by what mechanism obliteration of the pulmonary artery produces the symptoms of coronary thrombosis. It is impossible to answer this question finally. It seems, however, that pulmonary embolism produces a drop in intra aortic pressure and therefore a distention of the right side of the heart, which compresses the coronary vessels. Thus the same mechanism is called into play which in the case of pulmonary embolism is merely more complicated in origin than in coronary occlusion by thrombosis.

*New Clinical Form of Nicolas Favre Disease A Aravantinos—p 1918
Basal Fractures and Propidon M Lecercle—p 1918

Nicolas-Favre Disease—Aravantinos calls attention to a form of lymphogranulomatosis that is localized in the anorectal region and is acute. Its clinical manifestation is a dysentery. The patient first notices an increased frequency and loss of consistency of the stools. Soon painful tenesmus and loss of weight occur. Rectoscopic examination reveals an injected and ulcerated anorectal mucosa. Except for the tenesmus, the condition is less acute than bacillary dysentery. It is easy to understand that if not correctly diagnosed, the condition becomes chronic and results eventually in anorectal stenosis. The author believes that it is more frequent than generally believed and is probably caused by pederasty, since it is especially common in Greece among sailors.

*Abnormality of Knee Not Yet Described Accessory Sesamoid Patella Case D Vajano—p 1862
Symptomatic Treatment of Encephalitic Parkinsonism G Aschieri—p 1866

Abnormality of the Knee—Vajano states that there are no records in the roentgen or anatomic literature showing the existence of accessory bone formations at the inferior and anterior part of the knee. The cases reported in the literature as accessory bone formations of the patella are either doubtful cases of such a condition or instances of other processes, such as bone emigration, imperfect ossification and fractures, or pathologic processes of the patella. The author reports an abnormality of the knee consisting in the formation of an accessory or sesamoid bone having the form and structure of the patella and situated in front of the tuberosity of the tibia at the point of insertion of the patellar ligament. The bone formation which appeared in the right knee of a person who suffered trauma two years before showed in the roentgenogram as a dense, even bordered and dark triangular shadow in the lateral view and as a patellar opaque shadow in the front view.

The roentgenograms of the same knee taken seven months after the accident did not show it. There was no fracture of the patella, the superior epiphysis of the tibia or the tuberosity of the tibia. The form, volume and structure of the bone formation and the roentgenogram did not correspond to the presence of a bone fragment, post-traumatic ossification of the patellar ligament or juxta-tibial osteoma. The author believes that in his case the bone formation had a congenital origin but a traumatic determining cause, since the lateral roentgenogram of the left knee of the same person shows an almost imperceptible shadow of the same form and in the same location. The front view of the left knee shows nothing abnormal. The author makes a differential study of the origin, development and significance of congenital accessory and sesamoid bones from the point of view of embryology and anatomy, human as well as comparative, and names the condition "congenital inferior patella or patellar sesamoid bones."

Syndromes Following Phrenicectomy—Valdes Lambea, who has performed about 1,000 phrenicectomies, states that, in cases in which the diaphragm is immobilized by a radical phrenicectomy in an exceedingly high position, a syndrome may appear in the lung of the phrenicectomized side or in the blood. The pulmonary syndrome consists in atelectasis at the base of the lung, at the apex or at both, diminution of the respiratory murmur and presence of fine bubbling rales. Atelectasis is transient as a rule, but the rales are permanent. Because of the fact that the roentgenograms and the auscultatory signs of the syndrome are the same as those given by tuberculosis in evolution, the presence of the syndrome may be erroneously interpreted as a failure of phrenicectomy. The diagnosis is made by a comparison of the contrast that exists between the roentgenograms and auscultatory signs and the general improvement of the patient, proved by the lack of toxemia, cough, expectoration and fever and the normalization of the sedimentation speed of the erythrocytes. The hematologic syndrome following phrenicectomy in patients with tuberculous cavities containing caseous material consists in increased leukocytosis, with predominance of neutrophil granulocytes, and acceleration of globular sedimentation speed. The blood changes are due to the entrance of toxic material from the tuberculous foci into the circulation. The syndrome is transient and followed by improvement of the condition of the blood. The blood syndrome in patients in whom the toxemia is not intense consists in hyperglobulia with dyspnea and, in certain cases, with cyanosis. The number of erythrocytes rises, for instance, from 4,000,000 to 6,000,000, remains at the latter figure for some time and then returns to normal. Hemoptysis following phrenicectomy is rare. Only two cases of copious hemoptysis were seen by the author in about 1,000 phrenicectomies.

Anatomy of Radial Nerve at Region of Elbow Its Relation to Paralysis After Fractures I G Moreno—p 476
History of Surgery The Surgeon in Old Rome A Zeno—p 489

Spontaneous Amputation of Vermiform Appendix—Beluffi states that spontaneous amputation of the vermiform appendix is rare. He reports five cases seen in a group of 500 appendectomies, and in one the amputation was incomplete. He concludes that the amputation is caused by perforating appendicitis which perforates the entire wall of the organ in a given annular zone. Local and mechanical factors, such as infection and adhesions, either congenital or acquired, may be associated in producing the amputation. The lost tissues of the surfaces after amputation are replaced by granulation tissues, which obtrude the surfaces. The stumps of amputated appendices, as a rule, undergo neither obliteration nor reabsorption. The preservation of their vitality and anatomic structure is secured.

by the persistence of the meso-appendix and by the neovascularization from the surrounding organs to which they adhere. The stumps of amputated vermiform appendices are potentially pathologic and may be the starting point of acute inflammatory processes. Their removal during appendectomy is necessary to secure definite recovery of the patient.

Significance of Syphilis in Surgery as Revealed by Serologic Studies. L. Josa—p. 299

Embolism of Superior Mesenteric Artery—According to Okunj, embolism of the superior mesenteric artery is a rare and grave condition of the abdominal cavity causing death in the greater number of cases. The diagnosis of the condition is made difficult by the fact that the same symptoms occur in a number of other acute abdominal diseases, such as ileus or peritonitis. The existence of a failing heart, or an acute ulcerative or vegetative endocarditis or of an atheromatous aorta is of importance in arriving at the diagnosis. Embolism of the superior mesenteric artery occurs as a rule in advanced age. Early operation consisting of resection of the involved segment of the intestine is the only method that may result occasionally in recovery.

Chediak's Dry Blood Method for Diagnosis of Syphilis—Wendeborn directs attention to Dahr's report of that author's experiences with Chediak's dry blood method for the diagnosis of syphilis (abstracted in THE JOURNAL, March 31, 1934, p. 1113). Since Dahr stressed as the advantages of this method that it is simple, rapid, economical and reliable, the author decided to investigate these claims. He points out that the rapidity of the method and the inexpensiveness are convincing and he gave his attention to the problem of reliability and the question of whether the method is really simple enough to be suitable for the general practitioner. In tests in 575 cases he carefully adhered to Dahr's modified technic of the Chediak method. As comparative methods he used the Kahn test and the quantitatively evaluated Wassermann test. The dry blood method gave positive results in thirty-six cases of latent syphilis in which either one or both of the comparative tests had failed. Compared to this positive balance the dry blood method had a negative balance of seventeen cases. The author reaches the conclusion that in view of its reliability the dry blood method is valuable for group and first examinations and in cases in which a rapid diagnosis is desirable. However, he states that it is not suitable for the consultation hour of the general practitioner and emphasizes that the dry blood test must be made by persons thoroughly experienced in laboratory work. He points out that the method is especially valuable in the cases in which the patients object to the withdrawal of blood from the vein and in cases in which the suspicion of a withdrawal of blood for the diagnosis of syphilis is to be avoided.

*Treatment of Chronically Increased Intracranial Pressure. H. Roehagen—p. 2044

Value of Enucleation of Palatine Tonsils Determined in Five Hundred and Nineteen Cases. W. Zabel—p. 2046

Treatment of Increased Intracranial Pressure—Rosenhagen says that repeated spinal punctures are inadvisable in patients with increased intracranial pressure, because the reduc-

tion in pressure is not lasting, as the withdrawn quantity of fluid is rapidly replaced, quite often excessively ("artificial encephalohydrorrhea"), and repeated spinal punctures may thus favor the development of internal hydrocephalus. The author directs attention to other methods that make it possible to effect a reduction in pressure, such as the intravenous injection of hypertonic solutions of dextrose (40 per cent), magnesium sulfate (40 per cent) and sodium chloride (15 per cent). He describes several cases illustrating that the injection treatment with hypertonic solutions is helpful in chronically increased intracranial pressure of various origins, chronic meningitic conditions, serous meningitis, cases of increased fluid pressure in the ventricular system with and without hydrocephalus, sequels after cerebral apoplexy, cerebral tumors and their sequels, which are not amenable to surgical treatment, and disturbances that develop after concussion of the brain. He concedes that there are cases in which this treatment fails. In discussing the technic of the treatment, he says that the injection of magnesium sulfate frequently causes undesirable secondary effects, such as vertigo, anxiety and a feeling of heat or of suffocation. For this reason he gives magnesium sulfate and dextrose solution together. For instance, if 7 cc of dextrose solution is given, 3 cc of magnesium sulfate solution is administered, but if smaller doses are given, 1 or 2 cc of magnesium sulfate solution is administered with 3 or 4 cc of dextrose solution. In these combinations the injections are more effective than if dextrose solution is given alone. In cases in which the intravenous injection offers difficulties, the magnesium sulfate may be administered by rectum in a 45 per cent solution. It is advisable to mix 100 cc of this solution with 100 cc of oat meal gruel in order to facilitate retention in the rectum. In cases in which the administration of dextrose is inadvisable, as for instance in diabetes mellitus, the author injects 10 cc of a 15 per cent solution of sodium chloride.

Myosarcoma of Small Intestine. Case. G. von Knorke—p. 124

Results Following Choledochotomies—Bernhard reports 1,000 choledochotomies performed at the surgical clinic of the University of Giessen from 1895 to 1932. The numerical relationship between choledochotomies and cholecystectomies was as 1.5. The mortality was 9.9 per cent and was three times as great in men as in women. The most important cause of death was postoperative cardiovascular failure resulting from damage to the liver or pancreas. Peritonitis occupied a subordinate position as a cause of death. Icterus was present before the operation in 64 per cent, existed at some time in 17 per cent, and was absent in 19 per cent. The author considers icterus the most important indication for exploring the common duct. The common duct may be widened in the presence of a shrunken gallbladder or from pressure by enlarged lymph nodes. Stones were not found in 6.9 per cent, in 23.1 per cent they were present in the biliary passages alone, in 11.6 per cent in the gallbladder only and in 58.4 per cent in both the common duct and the gallbladder. The common duct was opened erroneously in thirty-five patients who had numerous small stones in the gallbladder. The author considers this indication for choledochotomy overrated. Stones were found in the common duct when the gallbladder was empty and shrunken. White bile was present in twenty-two cases and the mortality was twice the average. Stones were found in fifteen of thirty-eight patients who were submitted to a second choledochotomy. Choledochoduodenostomy is to be recommended for stricture of the lower end of the common duct and not as a primary operation for stones. An analysis of 180 deaths showed greater tendency to cholangitis in patients who have had several operations on the biliary tracts. Diabetes was more frequent after choledochotomies than after cholecystectomies. Liver cirrhosis developed later, and with greater frequency in neglected cases. Cancer of the liver and the biliary tracts developed fifteen years after the operation on an average, in twenty patients. Of 687 patients followed up, 389 recovered,

213 complained of mild symptoms and eighty-three complained of more pronounced symptoms. In order to determine the causes of postoperative morbidity, the author made functional studies of the contents of the stomach, determinations of sugar tolerance, and determinations of the lipase and diastase content of the blood. Actual recurrence of stones was rare. Persistence of symptoms was due principally to cholangitis and liver damage with an abnormal blood sugar curve. Chronic pancreatitis was present in more than 10 per cent. Subacidity and anacidity were found with particular frequency in the presence of pronounced complaints. In the treatment of postoperative complaints the author stresses the value of pepsin-hydrochloric acid and of a remedy consisting of a preparation of mercury, podophyllin, melissa, camphor and caraway.

*Sympathetic Disturbances Following Encephalography H Boeters—p 1829

Sympathetic Disturbances Following Encephalography—Boeters points out that the introduction of air into the cerebral ventricles causes, in addition to a general feeling of indisposition and occasionally vomiting, also temporary disturbances in the thermoregulation and in the sudoregulation. He says that Hoff called attention to the fact that encephalography produces experimental conditions, which, in connection with observations in cases presenting organic lesions of the brain, give some insight into the course and the interrelations of the central sympathetic regulatory mechanisms. In observations on human subjects and on animals, Hoff found that the morphologic blood picture is subject to a central regulation and that the cerebral irritation produced by the introduction of air causes a change in the entire sympathetic system with increased temperature and metabolism, acidosis, hyperthermia and hyperglycemia. At the same time there develop changes in the potassium, calcium and cholesterol values. The author decided to study the disturbances that develop as the result of the irritating action of the air introduced in the course of encephalography. He paid especial attention to the changes in the blood sugar values, making serial tests on forty five patients. He found that the introduction of air, irrespective of the quantity, caused a considerable hyperglycemia, but that after from one to two hours the original values had been reached again. The greatest increase in the blood sugar values (more than 100 per cent) was observed in children. In adults, the blood sugar values usually increased by from 40 to 80 per cent. However, in epileptic patients with hydrocephalus, in incompletely cured cases of dementia paralytica and in a case of Pick's atrophy, only a slight hyperglycemia was observed. Even cases of cerebral tumor with symptoms of pressure showed only slight increases. In discussing the significance of these observations, the author points out that the patients in whom the increase in the blood sugar was slight experienced only slight subjective discomfort. He thinks that this is due to the fact that, because of a change in the intracranial pressure the spontaneous sympathetic regulation had undergone a change in these patients. The hyperglycemia precedes all other sympathetic changes that develop after encephalography, that is, it is the most sensitive indicator of the irritation of the central sympathetic regulatory mechanism.

Determination of Urobilinogen in Stool—Fleischhacker and Seyfried mix the stool thoroughly weigh it and to 5 Gm add 1 cc of glacial acetic acid. Then they add 10 cc of alcohol (95 per cent) and 10 cc. of ether and filter the suspension.

To 2 cc of the filtrate, 2 cc of distilled water is added and from this is formed a series in geometrical progression, so that finally there is 2 cc of fluid in each tube. Then they add 1 cc of paradimethylaminobenzaldehyde to each tube. The reaction value is that degree of attenuation in the tube which just barely shows a rose color when held against a white background. In some cases the rose color is still rather intense in one tube whereas the following tube has not the slightest trace of it. In such cases the authors marked the reaction with a plus sign. They examined the reliability of this method in 148 cases by comparing the results in the attenuation series with the photometer values detected with Heilmeyer's method. It was found that when fresh stools were examined the two test methods did not reveal comparative values, but that there was a considerable degree of conformity between the results of the two tests when the stools were examined from three to eight hours after defecation. The authors explain this phenomenon and point out that tests with the attenuation series in fifty persons with normal hemoglobin metabolism gave values between 1 64 and 1 256, but they believe that the functional capacity of liver, intestine, bone marrow and other organs doubtless plays an important part. They think that values over 1 256 and under 1 64 are definitely pathologic and that even the values within the normal range may be pathologic (for instance, in case of severe anemia).

Treatment of Intra-Uterine Asphyxia—Hecht describes observations on a new-born infant that had attacks of asphyxia and respiratory arrest during the second week of life. He found that the cardiac mechanism had been greatly changed in that the normal transmission had been replaced by an atrio-ventricular automatism. After explaining the mechanism and effect of this automatism, he points out that, if the intra-uterine asphyxia has the same cardiac mechanism as the one he described in the infant, it too will have a tendency to elicit inspiratory movements, which, however, would be undesirable in this case because they would lead to the aspiration of amniotic fluid. He admits that intra-uterine asphyxia should be counteracted by obstetric measures by accelerating as much as possible the process of birth. However, it is also important to prevent the inspiration of amniotic fluid. He suggests that injections of atropine administered to the mother might counteract the atrioventricular automatism. Moreover, the mother should be told to make a hyperventilatory inspiration as often as possible. Oxygen inhalation on the part of the mother might also eventually be helpful, that is, all efforts should be made to depress the respiratory center of the fetus until the child is born and able to make its first inspiration. He stresses that cardiac stimulants should not be administered to the mother, because this would stimulate the fetal respiratory center and thereby lead to the aspiration of amniotic fluid.

Value of Some Carcinoma Reactions in Early Diagnosis of Uterine Cancer H Belobradsky—p 1612

*Treatment of Adrenal Insufficiency W Raab—p 1620

Cell Picture of Tuberculous Focal Reaction—Baar calls attention to Helmreich's studies on the so-called local blood picture, by which that author means the morphologic blood changes at the site of inflammation. In tuberculosis he examines the blood of a Pirquet papule, which he considers the manifestation of a perifocal reaction that has been projected to the skin. He thinks that the morphologic changes in the blood of the Pirquet papule reflect the reactions that take place in the surroundings of the tuberculous foci in the organism. The author considered it important to know whether the reaction of the organism is uniform throughout or differs in various regions of the body, or whether the allergic reaction may be limited to one organ. To answer this question, he studied the cytomorphologic changes in the tuberculous focus and compared them with the peripheral and local blood pictures. His studies were made on patients with tuberculous pleurisy and with tuberculous meningitis. He examined the pleural exudate and

the cerebrospinal fluid before an application of tuberculin and from twenty-four to forty-eight hours after an intrapleural or an intraspinal injection of from 0.1 to 0.5 mg of old tuberculin, blood specimens from the finger tip and from the Pirquet papule were examined at the same time. He describes and discusses the results he obtained in these studies and reaches the conclusion that the local blood picture according to Helmreich cannot be considered a projected perifocal inflammation, but he concedes that it provides a better insight into the processes that take place in the focus of the disease process than does the general blood picture. He also found that the allergic reaction may be limited to some organs and persists longest at the focus of the disease.

Treatment of Adrenal Insufficiency—Raab shows that in the treatment of Addison's disease it is possible to reduce the required quantity of cortex extract by the administration of comparatively large doses of sodium chloride (from 8 to 20 Gm each day). The use of sodium chloride seemed indicated in view of the reduction in the chloride content of the serum of patients with Addison's disease. He says that the sodium chloride may be given partly by intravenous infusion and partly by means of foods that have a high sodium chloride content. As another means of reducing the high cost of the treatment with adrenal cortex extract he suggests the use of the corticotropic hormone of the anterior pituitary, which is considerably less expensive. Since the pigmentation of Addison's disease does not yield completely even to a successful treatment with adrenal cortex extract, vitamin C preparations have been tried in order to counteract the pigmentation, but without satisfactory results. In this connection the author suggests that the hypophyseal pigment hormone might eventually be tried. He emphasizes that insulin treatment must be avoided in patients with Addison's disease because of their great sensitivity to this substance, relatively small quantities have been known to be fatal. The diet of patients with Addison's disease should be easily digestible and should contain large amounts of carbohydrates.

Influence of Physical Exertion and of Birth on Circulation and Metabolism of Pregnant Parturient and Puerperal Women W Franz—p 32

Rapid Pregnancy Reaction—Bruhl and Rieckhoff direct attention to the pregnancy test of Konsuloff, who found that hypophysectomized frogs become black following the injection of pregnancy urine into their lymph sac. The melanophore hormone eliminated in urine of pregnant women causes a diffusion of the pigment in the skin of the frog in from one to two hours. The blackening of the hypophysectomized animals becomes more noticeable because they become rather light following hypophysectomy. The authors decided to investigate the reliability of the Konsuloff test. In describing their method of hypophysectomy, they show that the hypophysectomized animals should be given several days to recuperate before they are used for the pregnancy test. In the testing of pregnancy urines the authors at first followed the directions given by Konsuloff, who claimed to have obtained results that were 100 per cent correct; however, they secured only fourteen positive reactions in twenty-five pregnant women. Further investigations disclosed that the concentration of the urine was highly important for the outcome of the test and a method was devised for the use of concentrated urine. The use of concentrated urine produced positive results in all cases of pregnancy and also in cases of carcinoma and in some cases of adenitis. Thus there is the dilemma that if unconcentrated urine is used the reaction will be negative in some cases of pregnancy, and if concentrated urine is used it will be positive in some conditions other than pregnancy. The authors reach the conclusion that the Konsuloff frog test is not sufficiently exact to replace the Aschheim-Zondek test.

Intermittent Physical Therapeutic Methods in Pulmonary Tuberculosis Ya O Kryzhevskiy B M Broderzon and M D Vainshtein—p 1743

Pulmonary Suppuration—According to Trefilov, abscess and gangrene of the lung represent various stages of essentially the same morbid process. Pulmonary suppurations run a variable course and present at times considerable diagnostic difficulties. The absence in the roentgenogram of a cavity does not rule out an abscess. In many cases roentgen examination reveals infiltration only. The diagnosis is made from clinical data, laboratory observations and the history. Grip and its complications play a predominant part in the etiology and pathogenesis of pulmonary suppuration. Grip pneumonias leave behind them pathologic alterations in pulmonary tissues which later favor the development of pulmonary suppuration. Of the author's thirty-two patients, 78 per cent gave a history of grip with pulmonary complications. The treatment consisted of injecting, on alternating days, 10 cc of a 40 per cent solution of methenamine in the cubital vein. At intervals of two or three days from 3 to 4 cc of blood was withdrawn from a cubital vein and injected in the cellular tissue of the chest. This was gradually raised to 10 or 12 cc. The author treated ten acute and eight chronic cases of pulmonary suppuration. Eleven of the patients were discharged as completely recovered, four were markedly improved, one was not improved and two died. The author considers this combined method the most effective of the conservative methods. He feels that it ought to be tried in all limited suppurations, acute and chronic, exclusive of cases characterized by cachexia.

*Terminal Stages in Diseases of Liver R Ehrstrom—p 651
Vaccination Against Typhoid Paratyphoid O Sievers—p 663

Neurology of Schizophrenia J Runeberg—p 690

*Senear-Usher's Disease Case R Wirkberg—p 709

Terminal Stages in Diseases of Liver—Ehrstrom treats of the terminal stages of hepatic disorders in four groups, the first of which is characterized by conditions in which infectious factors dominate, the second by a marked chronic jaundice, an 'icterus gravis,' with a grave disturbance due to the organism's inability to utilize the supplied fat as a contributing cause of death and of many symptoms including a possible hemorrhagic diathesis. In the third group are the cases with chronic portal stasis and constantly recurring ascites, together with an albumin hunger analogous to the fat hunger in the second group. The fourth form, relatively rare, is seen in the syndrome with acute onset and rapid fatal outcome designated in the literature by various terms such as cholemia, hepatargia, hepatic intoxication and la grande insuffisance hepatique' and depends, the author concludes, on an absolute hepatic insufficiency or hepatargia. He advocates omitting the term 'cholema' as a designation for hepatic disturbance to avoid unnecessary confusion and for the present rejects the term 'relative insufficiency' because as yet no sharply enough defined clinical picture corresponds to it.

Senear-Usher's Disease—Wirkberg says that about thirty cases of this disorder have been reported and describes the first instance to be reported from Scandinavia, in a man aged 24. On the face the disease localized to the nose and adjacent parts of the cheeks and was remarkably like lupus erythematoses. The scales, however, were softer and more easily removed, and on the trunk the condition greatly resembled pemphigus foliaceus. The elements were about the size of an almond and were covered by a thin soft crust. Treatment consisted in external application of potassium permanganate together with substances containing sulfur and tar, and in administration of calcium and arsenic. A complex carbamide compound of trisulfonic acid injected intravenously had no demonstrable by-effects. On discharge after two and a half months' treatment the processes in the face and anterior part of the trunk were almost completely healed, some loose crusts remained on the back.

A STATISTICAL STUDY OF 2,921 - CASES OF APPENDICITIS

MONT R REID, MD
D HEARY POER MD
AND
PAUL MERRELL, MD
CINCINNATI

From a study of a series of 842 cases admitted to the Cincinnati General Hospital from Jan 1 1915, to Jan 1, 1924, reported in 1926, it was deduced that (1) an unusually high percentage of cases entered the hospital presenting perforative appendicitis and its complications, abscess or peritonitis and (2) there still was some belief among our hospital staff that surgical treatment of appendicitis should be deferred for an interval rather than resorted to in the acute stage of the disease. This statistical study has been continued to include the years of 1924 through 1933 inclusive to determine whether the adoption in 1922 of immediate operation for acute appendicitis has changed in any way either of these deductions. We also present at this time our total statistics of this series of cases of appendicitis.

The series includes 2,921 cases of appendicitis admitted to the Cincinnati General Hospital between Jan 1, 1915 and Jan 1, 1934, a period of nineteen years. The vast majority of these cases have been treated in the surgical service of the hospital, although this number includes the few cases treated in the medical service. The preoperative, operative and postoperative data in the series have been studied in an effort to arrive at conclusions that may be of value in our subsequent treatment and are presented in the form of tables and charts.

PREOPERATIVE DATA

General—The number of cases of appendicitis admitted to the hospital has notably increased each year, so that in 1932 there were four and a half times as many admissions as there were in 1915, or an increase of approximately 350 per cent. Our charts show, as has been repeatedly shown before, that appendicitis is a disease of adolescent and young adult life, as two thirds (68.6 per cent) of the patients were between the ages of 10 and 30 years (chart 1). It occurred more frequently in children under 13 years than in any decade over 40. Only forty-three cases occurred in persons over 60. The disease is almost twice as common in males as in females. In this series 63.6 per cent of the patients were males and 36.3 per cent females. Race does not seem to be an important factor.

History and Physical Observations—One of the most striking observations in the preoperative data is the long interval of time that elapsed between the onset of the acute attack and admission to the hospital (table 1). With the knowledge of the disease that should be common to the physicians of the community, it is surprising to find that the average elapsed time between the onset of the attack and admission to the hospital is about four days (3.8 days, or 91.2 hours). When one breaks the series of acute cases into three groups—unruptured cases, perforated with abscess formation, and perforated with general peritonitis—the average elapsed intervals of time between onset of symptoms and operation are respectively 44, 129.6 and 80.64 hours. It is to be noted that the average elapsed time for the entire series was decreasing up to 1932 but that it has been higher during the past two years. This long interval is undoubtedly responsible for the high percentage of perforated appendices in the series and justifies the statement that, if results in the treatment of appendicitis are to be notably improved, physicians must advise and patients agree to earlier surgical treatment. It will subsequently be shown how advantageous it is from the standpoint of mortality, complications and period of hospitalization to operate before perforation of the appendix has taken place.

A review of the histories of 2,035 patients who entered the hospital with acute appendicitis shows that 837, or 41.12 per cent had had previous attacks while 1,198 or 58.88 per cent, entered in the first attack. When one considers that 42.5 per cent of the acute cases presented perforated appendices on admission, one realizes the danger of treating expectantly the first attack of appendicitis in the hope that it will subside.

With regard to the symptoms and signs of acute appendicitis, slightly more than half of our cases (53 per cent) presented what might be called a "typical" history (table 2). By that we mean the usual story of abdominal pain located most frequently in the epigastrium or around the umbilicus followed by nausea and vomiting, and localization of the pain in the right lower quadrant (McBurney's point). However, abdominal pain of some kind was the most frequent symptom, occurring in 94 per cent of the cases. Pain on pressure over the appendix was present in nearly 100 per cent of the cases, and we consider this the most important single symptom. When this tenderness is present the burden of proof is certainly on the examiner to show that it is not due to acute appendicitis. The pain of pressure, of course, varied a great deal in type, intensity and radiation. Muscle spasm and rigidity were usually, but not always, present. In some cases pain was elicited only on very deep pressure, in these cases the appendix was usually behind the cecum or in the pelvis. Nausea and vomiting are the next

most reliable symptoms, occurring in from 70 to 80 per cent of the cases. These symptoms occurred usually in the first few hours of the disease, but in some cases did not appear until late.

A rectal or pelvic examination was of great aid in establishing a diagnosis, tenderness, induration or a

TABLE 2—Clinical Data in Cases of Acute Appendicitis

Total Cases	Nausea	Vomiting	Abdominal Pain	Rectal Tenderness	Purgatives	Typical History
1460	1106 78%	1081 73%	1387 94%	653 44%	523 36%	778 53%

mass was felt in almost half of the cases (44 per cent). Rectal examination is of particular value in children in whom the diagnosis is frequently very difficult.

Approximately a third of the patients (36 per cent) (table 2) had taken some form of a purgative before admission to the hospital. Among 353 cases of acute appendicitis, studied during the past five years, in which a history of having taken purgatives was obtained, the incidence of perforative appendicitis was 34.3 per cent. This was considerably higher than the incidence of perforation among the other 656 acute cases treated during the same period, in which a history of taking purgatives was not obtained. Often the purgative was taken by the patient before seeking medical help, but altogether too frequently it was prescribed by the attending physician, apparently without regard for the consequences. Often the story was given us by a patient that he went to the "corner drug store" and was told by the druggist that he had "just the thing for the gas on your stomach." Radio announcements have not helped to reduce the mortality of acute appendicitis. In one day we heard forty-four different announcements over the radio for medicines which would relieve abdominal pain, gas, constipation, distention, and the like.

The average temperature, pulse rate and leukocyte count in the acute cases on admission show a very striking uniformity throughout the years (table 3). The temperature is rarely over 100 F. in simple, acute cases but may be much higher (102-104) in cases of gangrenous appendicitis and peritonitis. The temperature in children with simple acute appendicitis may be elevated to 102 or 103. The leukocyte count is found to vary with the degree of infection, being much more elevated in cases of gangrenous or perforated appendicitis.

OPERATIVE DATA

It is seen from table 4 that, of the 2,921 cases, 2,035 were diagnosed as acute and 810 as chronic, while in fifty-nine cases a mistaken diagnosis of appendicitis

was made. The diagnosis of these cases was made either at the operating table alone or at the operating table and in the laboratory. In seventeen cases in which operation was not performed, the diagnosis was made at the autopsy table. In the earlier histories it is rare to find a pathologic diagnosis other than that made at the operating table, but this is usually admitted to be sufficient.

Of the 2,035 cases of acute appendicitis in which operation was performed, 1,270, or 57.5 per cent, were found in all stages of acute inflammation, including gangrene, but perforation had not occurred, in 865, or 42.5 per cent, operation revealed that perforation had occurred and there was either a localized abscess or varying degrees of peritonitis. As will be seen in table 5 the yearly percentage of perforative appendicitis varied between 31 and 60 per cent. Just as the time interval between the onset of the attack and admission to the hospital has not decreased appreciably with the years, so the percentage of perforative appendicitis has likewise not appreciably diminished. There is seen to be a very close parallel in the increase of perforative appendicitis with the increase of time from onset of symptoms to time of admission to the hospital. Of the 865 cases which were found to be perforated at operation 576 (28.3 per cent of the total cases, or 66.3% of the total perforated appendices) presented localized abscesses, and 289 (14.2 per cent of the total cases, or 33.3% per cent of the total perforated appendices) presented varying degrees of peritonitis. The peritonitis was advanced and widespread in the majority of the cases.

TABLE 4—Pathologic Condition as Determined by Operation or Autopsy

Year	Acute	Chronic	Mistaken Diagnosis of Appendicitis	Autopsy Diagnosis	Grand Total
1915 to 1933	2,035	810	59	17	2,921

Seventy-two different surgeons operated in 2,806 cases of appendicitis, forty-one surgeons performed less than ten operations each, nine surgeons from ten to twenty operations, six surgeons from twenty to forty operations, and seven surgeons from forty to 150 operations. Nine surgeons performed 150 appendectomies or more. With such a large number of surgeons oper-

ating, the mortality of the individual surgeons varied greatly. The total mortality rate for all cases was 6.3 per cent for the nineteen years.

As was stated in the opening paragraph, the rule through the past several years has been to operate in all cases of acute appendicitis as soon as the diagnosis

has been established. The incisions used in operating for appendicitis have varied somewhat according to the tastes of the individual surgeons. Prior to 1922 the right rectus incision, was used as a routine whereas since 1922 the McBurney incision has been the routine incision. We believe that with almost no exceptions acute appendicitis can be adequately treated through the McBurney approach, whether it is an unruptured appendix, an appendiceal abscess or peritonitis. Operations so performed are less severe and postoperative complications such as obstruction, broken-down wounds and ventral hernias are less common. Adequate drainage is more easily and safely secured through a McBurney incision.

In 2,680 of the 2,806 surgical cases the appendix was removed at the primary operation, in 126 cases it was not removed. The diagnoses of the cases in which the appendix was not removed at the primary operation were (1) perforative appendicitis with abscess, eighty-seven cases, (2) perforative appendicitis with peritonitis, thirty-five cases, and (3) perforative appendicitis with peritonitis and intestinal obstruction, four cases. In fifteen of these cases the appendix was removed at a subsequent operation.

A description of the operations in this series will not be detailed. The common practice, as has been stated before, since 1922 has been to use the McBurney incision in all cases in which the diagnosis of appendicitis seemed more reasonable. The subsequent steps in this operation depend on the conditions found.

(a) Acute nongangrenous appendicitis. The appendix is delivered, the vessels of the meso-appendix are ligated with silk by the transfixion method and the meso-appendix is divided to the base of the appendix. A peritoneal cuff is dissected back from the base of the appendix, the appendix crushed, ligated with catgut and excised. The stump is treated with pure phenol (carbolic acid), followed by alcohol and inverted under a purse string suture of fine silk. A second suture or a series of Halsted mattress sutures is used to cover the inverted stump. Great care is exercised to cover

all raw surfaces, such as the divided meso-appendix. The peritoneum and muscular layers are closed throughout with silk.

(b) Acute unruptured gangrenous appendicitis. The same general procedure is carried out except that catgut is used for ligatures and suture material save for inversion of the appendiceal stump, where silk is always used. In the presence of turbid intraperitoneal fluid, drainage is never employed unless smears of this fluid show many organisms. If the removed appendix tested by water pressure shows no perforation, drainage is almost never employed, even though there may be some organisms in the turbid fluid. An exception to this rule is when grossly necrotic tissue must be left behind in the region of the removed appendix.

(c) Appendiceal abscess. An attempt is always made to remove the appendix, but in very ill patients the search for the appendix is not unduly prolonged. The abscess cavity is drained with cigaret drains and the wound closed very loosely with catgut about the drains. We are not sure that any closure of the wound should be attempted, for, as has been pointed out by others, sloughing of the tissues, due to the infection always present, may well be greater if sutures are used.

(d) Acute perforative appendicitis with peritonitis. The appendix is removed, if possible without too much manipulation, and drainage with soft cigaret drains is established through the McBurney incision. Care is exercised in the type of drain employed and its proper

placement, for it would appear that fecal fistula and intestinal obstruction are in part dependent on these factors.

The incidence of wound infection following operation in which drainage was not employed may be seen in table 6 as 0.06 per cent. In practically all these cases the infection was superficial to the muscular layers or

was a simple stitch abscess. There were only three instances of a completely broken down wound with evisceration of the intestine. It is interesting to note that all of these occurred through the right rectus incision. Twenty-three of these infections were in cases of acute gangrenous appendicitis presenting cloudy peritoneal fluid in which the wounds were closed without drainage. In none of these did peritonitis or a

on, with thirteen deaths, a mortality rate of 11.3 per cent. The total mortality rate for all the cases, including those in which operation was not done, was 6.4 per cent. It is to be noted that the thirteen patients who died in the nonoperative group had advanced peritonitis on admission to the hospital and died within the first twenty-four hours.

An examination of the operative mortality by one year periods shows a considerable variation. It is interesting to note the decrease in the mortality rate with the advent of the routine use of the McBurney incision in 1922. Prior to this time 409 patients with acute appendicitis had been operated on through a right rectus incision and the mortality rate was 9.5 per cent. Since 1922 there have been 1,626 patients with acute appendicitis operated on through a McBurney incision with a total mortality rate of 5.4 per cent. The significance of this contrast is slightly altered by the fact that the incidence of the cases presenting abscess and peritonitis fell from 51.3 per cent in the first series to 41.6 per cent in the second. While the decreased mortality cannot be attributed to the McBurney incision alone we feel convinced that the right rectus incision, by its greater magnitude and its attendant complications, contributed to the mortality of the very ill patients. It is sad to note, however, that there has been

an increase in the operative mortality during the past few years when the interval of time between onset of symptoms and operation has increased. This fact leads one to remember Garlock's¹ statement that "the mortality rate of acute appendicitis is directly dependent upon the length of time between the onset of symptoms and operation."

An examination of table 8 shows in a striking way the differences in the mortality following operations in the different varieties of appendicitis. In 1147 cases of acute unruptured appendicitis there were ten deaths, a mortality rate of 0.86 per cent (in the last 587 cases, three deaths, or a rate of 0.51 per cent), in 734 cases of chronic appendicitis there was one death, a mortality rate of 0.13 per cent, in 576 cases of perforative appendicitis with abscess there were sixty-six deaths, a mortality rate of 11.4 per cent, and in 280 cases of perforative appendicitis with spreading or generalized peritonitis there were ninety-five deaths, a mortality rate of 33.9 per cent. Keyes² has reported similar statistics with similar results. This difference in mortality is sufficiently striking to warrant the statement that, in the absence of very definite contraindications, operation is immediately advisable in all cases of nonperforative acute appendicitis. The mortality rate in such cases (0.86 per cent) does not warrant the waiting for an "interval" in the hope that the acute attack will subside.

Chart 2—Days of hospitalization in acute unruptured, acute ruptured and chronic cases of appendicitis.

Chart 1—Age periods of patients in the series.

localized abscess develop. This low percentage of infection would justify the statement made previously that drainage in these cases is not necessary. The incidence of infection has decreased since 1922 in spite of the fact that in acute cases without cloudy fluid and in chronic cases the wounds have been closed with silk as a suture material.

The complications that accompanied the primary condition on the admission of patients, or developed subsequently, form a large and miscellaneous group: tuberculous peritonitis, four cases; fecal fistula, twenty-

nine, intestinal obstruction, twenty-three, subphrenic abscess, thirteen, liver abscess, eight, pneumonia, thirty-two, pulmonary embolism, four, pelvic abscess, forty-five, and numerous other complications. Fourteen cases occurred in pregnant women with only one abortion.

The mortality data are presented in table 7. In the nineteen year period from 1915 to 1933 inclusive, 2,806 patients with appendicitis were operated on with 176 deaths, or an operative mortality rate of 6.3 per cent. One hundred and fifteen patients were not operated

1 Garlock J H. Acute Appendicitis. Controllable Mortality Factor. *Ann Surg* 23: 248 (Feb) 1934.
2 Keyes E L. The Mortality from Appendicitis and the Cause of Death Following Appendicitis. *Ann Surg* 99: 47 (Jan) 1934.

From a purely economic standpoint early diagnosis and operation are very important. The average total days of hospital stay in cases of acute unperforated appendicitis was 8.21 days, whereas in those presenting perforation and formation of abscess or peritonitis the average hospital stay was 27.3 days (chart 2).

SUMMARY

In a report of 2,921 cases of appendicitis admitted to the Cincinnati General Hospital it is noted that appendicitis is a disease of adolescent and young adult life and that it is twice as common in the male as in the female.

The average elapsed time (38 days) between the onset of symptoms and admission to the hospital was much too long for proper surgical treatment and the mortality rate will remain high as long as patients are not operated on earlier. Complications will also be frequent and the hospitalization period long.

Approximately 60 per cent of the acute cases were admitted during the first attack and approximately 40 per cent of all cases were admitted after the appendix had ruptured. These facts reveal the danger of expectant treatment.

The use of purgatives was found to lessen very definitely the patients' chances of recovery. The incidence of perforation and death was much higher among those who had taken cathartics.

In more than 40 per cent of the cases of acute appendicitis, perforation had occurred before admission to the hospital and the percentage of perforations has decreased very little during the last few years. Over 98 per cent of the deaths from appendicitis were due to the complications accompanying perforation.

The mortality rate in acute unruptured appendicitis (0.86 per cent) was low in comparison with the mortality rate after rupture (with abscess formation, 11.4 per cent, with peritonitis, 33.9 per cent).

The death rates for cases presenting abscess and general peritonitis are very high in comparison with the rates reported by many surgeons who have adopted the more conservative methods of treatment. Since this study was made we have been using the conservative or Ochsner³ treatment for the cases in which we have thought it was indicated, and it will be interesting to make a comparison of the death rates at a later date.

Scientific Prognosticators—It is an all too common practice of scientific publicists and prognosticators to give free vent to their imaginations in a most unscientific way by picturing our descendants as flying through interplanetary space or banishing old age by administration of glandular extracts. No doubt many of the past triumphs of science were relatively to the times as spectacular and even more unexpected than these would be. However scientific progress is not a great leap of imagination but a steady process, like the advance of a great army at times strategic positions are captured, as when the positive electron (positron) was discovered at times there is a steady mopping up process all along the line as when the systematic search for chemical isotopes followed the first discovery at times there is retreat, as when a theory is proved untenable at times a new powerful engine of this scientific war is invented like the radio tube amplifier. While the scientific campaign is generally well planned in advance and directed toward certain main objectives, it is also on occasion opportunistic in that its center of activity may be quickly shifted by some new discovery or idea which discloses new territories to be conquered—Compton, Karl T., President Massachusetts Institute of Technology. What's Next in Science? *Ital. Spec.* 2: 250 (Jan. 27) 1936.

THE PROBLEM OF NERVOUS AND
MENTAL SEQUELAE IN CARBON
MONOXIDE POISONINGFREDERICK H. SHILLITO, M.D.
CECIL K. DRINKER, M.D.

AND

THOMAS J. SHAUGHNESSY
BOSTON

In seeking information concerning the incidence and characteristics of nervous and mental sequelae following carbon monoxide poisoning, one is aided only in a limited way by the literature. It is true that there is virtual agreement as to the pathogenesis of the lesions in the brain following fatal acute carbon monoxide poisoning. As Haldane¹ points out, degenerative changes are caused by anoxemia of the brain as the result of the fact that much of the circulating hemoglobin is combined with carbon monoxide to the exclusion of oxygen. Throughout the brain there are areas of perivascular and perineuronal edema with varying amounts of nerve cell degeneration together with small hemorrhages due to diapedesis of red blood cells. The changes apparently are most marked in the corpus striatum and cortex. These pathologic changes, however, describe cases of fatal poisoning. In contrast, almost no information is available concerning the pathologic changes in human cases in which the acute stages of carbon monoxide asphyxia are survived.

With regard to the actual incidence of permanent after-effects in carbon monoxide poisoning, unanimity of opinion is not found. The more comprehensive monographs on the subject² usually present conclusions drawn from cases reported in the literature rather than from cases actually seen by the authors.

Glaister and Logan,² twenty years ago, made sweeping statements of severe nervous and mental sequelae following acute or chronic carbon monoxide exposure. Sayers and Davenport² in 1930 cited from the literature cases showing after-effects. Certainly a considerable number of cases of sequelae in carbon monoxide poisoning are not in the possession of any one observer or at least, if so, have not been reported. Rossiter,³ during nineteen years' experience as company surgeon for the Carnegie Steel Company, observed 2,000 cases of carbon monoxide poisoning, which he reported in 1928. Only four patients had any after-effects beyond a few days of transient headache and weakness. In three of these four cases complete recovery occurred within two weeks. One patient, he reported, had a permanent psychosis. He felt sure that except in rare instances a patient, if not dead when found, can be resuscitated and will suffer only a few days of transient after-effects.

Our purpose in this paper is to contribute to an understanding of the incidence and characteristics of

From the Department of Physiology, Harvard School of Public Health and the Department of Medicine, Columbia University College of Physicians and Surgeons.

Cooperation was extended to the authors by the following members of the directing staffs of the hospitals visited: R. E. Blasdel, M.D., David Corcoran, M.D., Ralph P. Folsom, M.D., H. B. Lang, M.D., Willis F. Merriman, M.D., George W. Miller, M.D., Charles S. Parker, M.D., and William J. Tiffany, M.D. Many others helped in the course of this investigation.

after-effects of carbon monoxide poisoning. It is obviously important to any practitioner to know something about the prognosis of a patient acutely poisoned with carbon monoxide. What are the chances that he will escape serious after-effects, such as psychoses or paralyses? In addition, the entire question of the sequelae of acute carbon monoxide poisoning is a serious medico-legal problem at the present time.

TECHNIC OF INVESTIGATION

An investigation of the after-effects in cases of acute poisoning presents certain inherent difficulties. Serious after-effects are exceptions rather than the rule. The commonly experienced headache and weakness pass off in two or three days. In certain instances, however, serious manifestations do appear, either immediately or a few days after the accident. In order to uncover any considerable number of the latter cases it is necessary to have data on many thousands of cases of acute poisoning. We have such a collection of records covering the accidents occurring in the metropolitan area of New York City for a ten-year period. This collection is unique and probably cannot be duplicated elsewhere.

TABLE 1—Carbon Monoxide Calls Made by Emergency Squads of Various Gas Companies in Metropolitan New York Area

† Returns incomplete

The New York metropolitan area is preeminently suited for this undertaking. Table 1, covering the ten-year period from 1925 to 1935, shows the number of calls made by the emergency crews of the gas producing companies of New York. Each of these calls indicates a carbon monoxide exposure.

In order to locate the cases showing mental and nervous sequelae, a search was made through the records of the seven state institutions that serve the New York City area. Records of forty-three cases were found in these seven hospitals. Each case represented unquestionably the after-effects of acute carbon monoxide poisoning. Of these patients, thirty-nine were poisoned during the ten-year period 1925-1935, while four were poisoned either before or after this ten-year period. In the same period there were more than 21,000 carbon monoxide exposures in the same area. Furthermore, there were more than 80,000 admissions to mental institutions drawing patients from this area. Of these 80,000 patients only thirty-nine owed their psychoses and neurologic signs to carbon monoxide poisoning. It is immediately apparent that nervous and mental sequelae sufficient to hospitalize a patient do not commonly follow carbon monoxide asphyxia.

Before presenting the results of the investigative work, it is well to describe the usual way in which cases of carbon monoxide poisoning are handled in the metropolitan area of New York City. The person, most often one attempting suicide, is discovered by

friends or neighbors, who notify the police and ambulance service. These calls are relayed immediately to the maintenance stations of the emergency squads of the gas companies of the area, which maintain crews that are highly trained in resuscitation measures and are provided with approved inhalation apparatus. They respond to all calls arising from gas leaks, fires, and the like, and arrive at the scene with the fire companies and police. Emergency treatment is immediately started, consisting, in brief, of prone pressure artificial respiration and inhalation of 93 per cent oxygen and 7 per cent carbon dioxide, and is continued until the case is disposed of by the ambulance surgeon. The more serious cases are usually removed to a hospital for a few days' observation. Should the patient show any signs of a toxic psychosis on recovery from the acute poisoning he is transferred to a psychiatric ward for diagnosis. If the psychosis is persistent, he is transferred by court order to one of the state mental institutions for further treatment. Here an examination includes a complete history of the type advocated by all first class teaching hospitals. Any laboratory investigation may be ordered by the attending physician. The physical examination is complete. Whenever indicated, special examinations, such as neurologic, gynecologic or ophthalmologic, are carried out by visiting consultants. Throughout the stay in the hospital, progress notes by the attending physicians appear on the hospital record. In addition, the complete minutes of the discussions of the patient before the staff conferences are included. When the patient is at home on parole, in the care of a friend or relative he is seen in the outpatient department. If he remains well he is discharged from the hospital service in about one year. In the case of deaths, no autopsies sufficiently complete to be included in this study were reported.

INVESTIGATIVE RESULTS

Records were studied in seven state mental hospitals near New York City: Brooklyn State Hospital, including Creedmore State Hospital, Manhattan State Hospital, Hudson River State Hospital, Central Islip State Hospital, Kings Park State Hospital, Rockland State Hospital and Pilgrim State Hospital. These hospitals were chosen because practically every admission of persons for mental illness in the metropolitan area of New York occurs in one of this group. Through the cooperation of the officers of the various institutions named, every record with the diagnosis of "psychosis due to drugs and other exogenous toxins (carbon monoxide or illuminating gas)" was examined. In one institution every record of patients in the hospital on that day was reviewed for even a mention of "gassing" at some time in the life of the patient. This undertaking meant that some 6,000 records were reviewed, each physician in charge of a unit in the institution being made responsible to uncover the mention of gassing among the records of the patients in his charge. By this means from the 6,000 cases in the hospital on that day twenty-four were sifted out. Each of these case records was reread by one of us. In each of them the gas exposure—usually a suicidal attempt with the patient simply snatching at the stove in order to turn on the gas—had absolutely nothing to do with the psychosis. The psychoses in these patients varied and antedated the gas exposure in every instance. As a result of this examination of the records of patients in one of the hospitals we have felt very confident that all cases pertinent to our study could be uncovered by the diagnosis index of the various institutions.

INCIDENCE OF SEQUELAE AFTER CARBON
MONOXIDE POISONING

In table 2 the admissions by fiscal years of six of the seven mental hospitals are tabulated. Admissions to Pilgrim State Hospital are omitted because the patients are usually received from other mental hospitals. All transfers in the case of Rockland State Hospital are likewise excluded. In these hospitals, drawing from the metropolitan area of New York City, there were 81,659 admissions in the ten-year period of 1925 to 1935. Included in this number were thirty-nine cases of psychoses due to carbon monoxide poisoning. (An additional group of four cases, in which poisoning occurred either before or after the ten-year period, is not included in these tabulations concerning the incidence of sequelae.) The ratio of carbon monoxide psychoses to all other psychoses gives the incidence percentage of 0.05 per cent, or roughly one carbon monoxide case to 2,000 other psychoses.

The incidence of sequelae of carbon monoxide poisoning in relation to the total number of acute cases has been computed. During the same ten-year period approximately 21,000 poisonings occurred. Among these, thirty-nine cases of carbon monoxide sequelae appeared. From these facts it appears that one case in 500 acute exposures later showed nervous or mental symptoms. One third of the 21,000 patients could not be resuscitated. Such a low incidence of sequelae and such a high incidence of fatal cases indicate that persons are apt to succumb to the acute poisoning or recover completely.

CLINICAL CHARACTERISTICS OF THE NERVOUS
AND MENTAL SEQUELAE FOLLOWING
CARBON MONOXIDE ASPHYXIA

The entire forty-three cases of nervous and mental sequelae can be examined in order to draw a composite picture of the clinical syndrome. The symptoms are those that have followed acute carbon monoxide poisoning after the usual transient effects have disappeared. This complex is entirely different from so-called chronic carbon monoxide poisoning caused by the inhalation of a low percentage of gas over a prolonged period of time. During this investigation no cases of nervous or mental sequelae were found to follow such "chronic" and mild exposure. All the patients in our series were affected sufficiently to require admission to mental hospitals.

Age of Patients—The average age of the forty-three patients was 53 years. The youngest was 20 and the oldest 83. The eleven patients dying within two years following poisoning were on an average 61 years of age. The average age of those surviving a two-year period was 50 years. Complications such as bronchopneumonia occur more frequently in the older group.

Sex of Patients—Of the total of forty-three cases, twenty-seven were men and sixteen were women.

Nationality of Patients—Among these patients there were eleven Americans, seven Irish, five Germans, five Jews, two Austrians, two Italians, two Bohemians, two Negroes, two Chinese, and one Norwegian, one Finnlander, one Greek, one Dane and one Swede.

Past History—Of the forty-three patients, nine were alcoholic, while eleven indulged in alcohol moderately. Twenty-two were total abstainers. No information was available with regard to one patient. Acute alcoholism, of course was often the direct cause of the overwhelming exposure of the patient at the time of the acute poisoning. Otherwise, alcohol played no contributory

part in after-effects of carbon monoxide asphyxia. In other regards the past histories of the patients were not enlightening.

The Degree of Acute Poisoning Necessary to Cause Sequelae—It is now generally agreed that carbon monoxide is rapidly expired from the body as soon as the person is removed from the poisonous atmosphere. The assumption is fair that damage to body tissues which can produce any after-effects occurs during the period of acute asphyxia. Irreversible changes must be produced during this period. All the patients in this series were unconscious when discovered. By itself, this is strong evidence that a deep intoxication precedes any after-effects. Often the poisoning occurred under the most unfavorable situations, such as suicidal attempts, alcoholic intoxication, and in sleep. These situations favor deep intoxication with carbon monoxide gas. The impression that a period of unconsciousness from a large dose of carbon monoxide gas characterizes the acute poisoning in all instances in which after-effects are sufficiently serious to bring the patient to a mental hospital is substantiated by remarks appearing on the hospital records, such as "unconscious

TABLE 2—Total Admissions in Ten Year Period in Mental Hospitals Serving New York Metropolitan Area, Including Psychoses Due to Carbon Monoxide Intoxication

* Exclusive of transfers.

two days" "unconscious four days" "for several days lapsed off into semiconsciousness," and "resuscitated after eight hours."

The records of twenty-two of the forty-three patients who were resuscitated by the emergency crews of the gas companies serving metropolitan New York have been available to us and provide reliable information concerning the episode of acute poisoning.

Every one of the twenty-two patients was unconscious when first discovered and fourteen were in the deepest coma from the gas inhaled. The experienced observer would realize that these fourteen patients were in the most desperate condition and a few more minutes' exposure would have caused a fatal issue. They presented the following "in extremis" condition: complete unconsciousness, with a slow or irregular pulse and with a slow gasping respiratory rate. Often artificial respiration, in addition to oxygen-carbon dioxide inhalation, had to be resorted to during the treatment. The eight other cases showed a clinical picture of less severe acute carbon monoxide poisoning. In these the patients were unconscious when discovered, but the other signs were less disturbing. The pulse was moderately elevated and the respirations were about the normal rate.

Further information concerning the degree of acute poisoning necessary to cause after-effects can be secured by examining the length of time required by the emergency squads to establish sustained normal breathing.

in the patients. By simply adding up the number of minutes of prone pressure, inhalation treatment, or both, in each case, the figure of sixty-six minutes per patient in our series was secured. On the individual cases the time varied from a low of twenty-five minutes to a high of 195 minutes. These figures may be compared with the time of resuscitation in fifty cases treated by the emergency crews picked at random over the last five years. This average was thirty-four minutes. The longest treatment in these cases was 145 minutes and the least was twenty minutes.

Onset of Sequelae of Carbon Monoxide Poisoning—The great majority of patients who are brought into hospitals after emergency resuscitation are entirely conscious. They experience several days of unpleasant but entirely transient effects. These symptoms consist of headache, dizziness and, perhaps, gastric distress with nausea. It has been quite conclusively demonstrated by Forbes, Cobb and Fremont-Smith⁴ that these symptoms are due to cerebral edema induced by the poisoning. Such cases show no serious after-effects.

In our forty-three cases there is reliable information concerning the first week following the acute poisoning in all but eleven.

The exact time of the onset of symptoms of nervous and mental sequelae in carbon monoxide poisoning is variable. Two classes are seen: (1) those cases with the onset of symptoms within one week and (2) those cases with the onset of symptoms after a clear period of from one to three weeks. In the total of forty-three patients, nineteen suffered after-effects within the first week while thirteen experienced a clear period. In eleven instances insufficient data were available for analysis.

The cases that showed symptoms within the first week usually had no clear period. The group of nineteen included most of the patients so severely poisoned that their unconsciousness lasted several days. On recovering from the comatose state they passed immediately into a confused and disoriented state. Furthermore, neurologic signs were occasionally detectable.

Case 1 illustrates the immediate onset of after-effects of carbon monoxide poisoning following the acute episode.

A week or more of mental clarity following acute poisoning is an interesting phenomenon. This group of thirteen cases may be sharply differentiated from the group just discussed. The patients recovered completely after the acute episode. Many were discharged from the hospital and some even returned to their jobs. There was an abrupt onset of secondary symptoms on about the tenth day. Cases 2 and 3 are illustrative. The longest period of clarity was nineteen days. In two instances there was a sudden onset of symptoms suggesting intracranial accident, in both there was collapse with focal muscular paralysis. These accidents were serious and caused permanent paralysis or death.

THE TYPICAL PSYCHOSIS FOLLOWING CARBON MONOXIDE POISONING

A psychosis, most usually temporary in character, was the most common manifestation of the after-effects of carbon monoxide poisoning. In every instance the psychosis was quite similar. It was marked by confusion and bewilderment, combined with a loss of memory. The events occurring at the time of the accident were forgotten. Such symptoms as hallucinations

and delusions were conspicuously absent. At times there was overactivity of short duration. The entire psychosis was brief. Improvement was usually noted by three months after the accident. Indeed, improvement was observed in some cases within a few weeks. In some, improvement was not seen for six or eight months. It is quite evident that the psychosis assumed its most severe form at the onset. The patient rapidly sank to the level of a vegetative existence, incontinent, untidy, unresponsive and unable to carry out any voluntary acts. From this state he often improved within a few weeks, so that he was walking about the ward. Disorientation and confusion would disappear before the memory defects. The latter were the last to clear and sometimes months or years passed before the events immediately surrounding the accident could be recalled. Within a year most of the patients were sufficiently improved so that they could be paroled home.

Amnesia in some form was the most regular feature of the psychosis following carbon monoxide poisoning. Usually, as already noted, it consisted of memory defects.

One case showed an auditory aphasia. In the literature deafness is often mentioned as a sequel of carbon monoxide poisoning. In this instance the deafness was actually an auditory aphasia and not a primary nerve injury. There was also an accompanying motor aphasia that cleared in a week's time.

Neurologic Changes in Carbon Monoxide Poisoning—The forty-three cases showed a fairly high incidence of neurologic changes in varying degrees of severity. The least apparent lesion—if it deserves the title—was marked by increased reflexes alone. From these minimal symptoms the cases graded upward to well advanced parkinsonism, with increased reflexes, slow movement, lack of coordination, fixed facies and scanning speech. We have encountered occasional hemiplegias and paraplegias.

In addition to these changes denoting muscular hypertonia, and indicating basal ganglion lesions, muscle atrophies and skin hyperesthesias were found.

The neurologic lesions appeared early in the course of the disease, along with mental manifestations. The neurologic picture showed steady improvement, leading often to complete recovery from within a few days to several years, depending on the degree of the lesions. Usually the cases showing only increased reflexes cleared within a few weeks. Six of the forty-three cases, however, showed permanent neurologic residua. In five instances these permanent effects consisted in parkinsonism and in one instance simply increased reflexes. Ten patients died early in the course of the disease, because of a combination of the gas poisoning and senility resulting in terminal bronchopneumonia. It is difficult to analyze the degree of neurologic damage in these patients because of the comatose, moribund condition. Definite neurologic signs were demonstrated in three of these cases.

Omitting patients who died, twenty-three showed neurologic signs, six of whom did not fully recover and seventeen of whom recovered completely (table 3). Case 4 illustrates marked neurologic lesions.

End Results in Carbon Monoxide Poisoning—For clarity the forty-three patients are divided into "dead," "recovered" and "permanently affected." The two year period following the individual's exposure to carbon monoxide is arbitrarily designated as the period beyond which signs and symptoms are considered permanent. Of the forty-three patients, twenty-three recovered

⁴ Forbes H S, Cobb Stanley and Fremont Smith Frank. Cerebral Edema and Headache Following Carbon Monoxide Asphyxia. Arch Neurol & Psychiat 2: 264 (March) 1924.

eleven died, and nine suffered permanent effects. In evaluating the final results in these cases it has been necessary to rely entirely on hospital records. The criteria of complete recovery has been the hospital note of discharged as "recovered." In each case there was a year's follow up, and notes made by physicians from the hospital gave a good indication of the adjustment that the patient made after leaving the hospital.

Eleven of the patients died within two years of the date of the acute poisoning. A glance at the first ten in table 4 shows that they all died within three months of the acute poisoning. In all but two of these deaths

TABLE 3—Incidence and Type of Neurologic Lesions Occurring Following Carbon Monoxide Poisoning

Total		43

was attributed to bronchopneumonia or senility. Two of the patients, 2 and 6 in the table, died from primary brain tissue destruction.

The last and eleventh case on the list was very unusual. A man, aged 39 approximately six months after carbon monoxide poisoning presented little data as to his health other than that he had been in a private sanatorium. On admission to the state mental hospital he was found to have marked neurologic signs as well as a psychosis. He was completely incapacitated. A blood examination showed a picture of primary anemia. In spite of temporary improvement on liver therapy he continued to be very weak and died sixteen months after the poisoning.

Twenty-three of the cases were paroled or discharged without, apparently, any permanent scars of poisoning.

Of the total forty-three cases, nine fell into the group of permanent sequelae. Five of these nine patients suffered from neurologic complications. This consisted of a modified parkinsonism, with stiffness of extremities due to muscular hypertonia. Three of the patients suffered from psychoses, one of which was an auditory aphasia. The ninth case showed both neurologic and mental lesions.

Prognosis in Carbon Monoxide Poisoning—This investigation covering the after-effects in 21,000 cases of acute carbon monoxide poisoning leads one to believe that the prognosis as to sequelae is not alarming. We found only forty-three patients who suffered enough after-effects to be admitted to mental institutions.

Furthermore, if a patient does fall into the small group of cases that show sequelae, he still stands a good chance of complete recovery within two years. It is usual that nervous tissue damage is maximum at the time of the destruction. From then on regeneration takes place, unless the pathologic process continues. Hence, in cases of carbon monoxide nervous and mental disabilities, hope of improvement should be entertained. After a two year period the condition is most likely to be static.

GENERAL SUMMARY

The New York metropolitan area was chosen for a study of nervous and mental sequelae of carbon monoxide poisoning. It is known that at least 21,143

acute exposures of all degree occurred there in a ten year period. For the same period a survey of the state mental institutions serving the metropolitan area of New York City showed thirty-nine certain cases of sequelae of carbon monoxide. Such patients formed 0.05 per cent of the total admissions. Serious mental or nervous sequelae of carbon monoxide poisoning are thus infrequent in relation either to other nervous and mental diseases or to the number of acute exposures.

Study of case records revealed that when nervous or mental damage occurred the acute carbon monoxide intoxication was extreme. Complete unconsciousness was invariable and the most active resuscitative measures were necessary. None of these cases followed so-called chronic carbon monoxide exposure over a long period of time.

A clear period of from seven to twenty days preceded the onset of symptoms in one third of the cases. In the remainder of the cases the symptoms started immediately following the poisoning.

Mental sequelae consisted of a confusion psychosis, with disorientation, lack of judgment and amnesia. Motor overactivity and aphasia were much less common. Hallucinations, delusions or convulsions played no conspicuous part.

Nervous sequelae consisted of signs varying from slightly increased deep reflexes to well advanced parkinsonism. Sensory disturbances, such as skin anesthesia and peripheral motor neuritis, were also encountered. These cases all showed improvement, but the final result depended on the degree of initial damage.

In the total group of forty-three cases, twenty-three patients recovered completely, nine suffered permanent nervous or mental sequelae and eleven died.

ABSTRACT OF CASES

CASE 1—Showing immediate onset of sequelae. A man, aged 69, single, a German waiter, with no history of alcohol or drugs, had had no occupation for three years because of general weakness and senility.

TABLE 4—Analysis of Cause of Death in All Patients Dying Within Two Years of the Acute Poisoning

Patient	Age	Duration of Illness, Days	Cause of Death
1	40	3	Bronchopneumonia

The patient is believed to have attempted suicide because of "pain." He was found in a gas filled room unconscious, with a pulse of 100, and respiration rate of 12 per minute. He was revived after considerable effort. It was necessary to institute artificial respiration in addition to thirty minutes of inhalator treatment (oxygen 95 per cent and carbon dioxide 5 per cent for twenty minutes, 90 per cent oxygen and 10 per cent carbon dioxide for ten minutes). He was removed to Bellevue Hospital where he was immediately seen to be confused, disoriented and mentally incapacitated.

On the nineteenth day he was admitted to the Manhattan State Hospital from Bellevue Hospital. On admission the patient was semie emaciated and bedridden. He was mentally confused, with no judgment. The blood pressure was 115 systolic, 75 diastolic. The heart sounds were noted as faint. The reflexes were normal. Urinalysis showed a specific gravity of 1.017, albumin 1 plus, and an occasional red blood cell in the sediment. The Wassermann reaction was negative.

On the forty-second day the patient died of bronchopneumonia and cardiac decompensation.

The diagnosis was psychosis due to drugs or other exogenous toxins (illuminating gas) and confusion.

CASE 2—Showing onset of symptoms after a "clear" period A man, aged 37, Irish, separated from his wife, had a history of habitual use of alcohol, otherwise his past history was irrelevant.

While intoxicated the patient and his brother were overcome by escaping gas. When discovered the patient was unconscious, pulse irregular and the respiration rate 6 per minute. Oxygen 95 per cent and carbon dioxide 5 per cent were administered by an inhalator for one hour. He was removed to City Island Hospital, where he is reported to have been unconscious for two days. For the remainder of the first week he apparently had a "clear" period and seemed to be entirely recovered.

On the seventh day the patient began to "act queerly." He was transferred to Bellevue Hospital. Mentally he was unresponsive. A right positive Babinski sign was noted.

On the forty-second day he was admitted to the Manhattan State Hospital from Bellevue Hospital. On admission he was comatose. Only a partial physical examination was carried out. Mentally he was dull, apathetic and completely disoriented.

On the eighty-fourth day his condition was improved. He was out of bed, wandering about the ward.

On the 133d day he was almost fully recovered. Memory and orientation were good.

On the 166th day he left the hospital on parole.

On the 265th day he was "as well as ever."

On the 584th day he had a complete discharge from the hospital as recovered.

The diagnosis was psychosis due to drugs or other exogenous toxins (illuminating gas) and confusion.

CASE 3—Showing a "clear" period A woman, aged 51, a Danish housewife, did not have a contributory past history. She was found unconscious from illuminating gas exposure and removed to the hospital, where she remained unconscious for from forty to fifty hours. After five days she was discharged from the hospital, apparently entirely recovered from the gas poisoning, except for a little weakness. In two weeks, however, her gait became unsteady and her mental state changed from clarity to confusion and bewilderment. She was admitted to another hospital for observation. There it was found that she was mentally confused.

On the fifty-second day she was transferred to the Hudson River State Hospital. On physical examination on admission no remarkable changes were noted except on the neurologic side. In this respect there was a noticeable blank expressionless appearance to the face. The knee jerks were increased. There was a coarse tremor of the hands. Skin sensitivity to touch, cold and heat was diminished over the entire body. Mentally the patient was abnormal. She was anxious and disoriented. There were no hallucinations or delusions. Urinalysis showed a specific gravity of 1.021, a faint trace of albumin and no sugar, and the sediment was clear. The Wassermann reaction was negative.

On the fifty-ninth day the progress note said that the patient had cleared mentally so that she was well oriented and more interested. She complained of vague pains over the body.

On the ninety-fourth day the progress note said that the patient felt that she was thinking more easily. She was mentally clear on examination. On the 116th day all neurologic signs, including the diminished skin sensitivity, had cleared.

On the 123d day the patient was paroled.

On the 266th day the patient reported that she was feeling better every day. She was going to movies and the like.

On the 490th day she got her permanent discharge papers.

The diagnosis was psychosis due to drugs or exogenous toxins (illuminating gas) and confusion.

CASE 4—Showing marked neurologic signs with permanent disability A woman, aged 47, a German housewife, with two children, had no history of addiction to drugs or alcohol. She had had menopausal symptoms for one year.

The patient attempted suicide by slashing her wrists and exposing herself to illuminating gas in her apartment. She was discovered unconscious, with a pulse of 115, respiration rate 6 per minute, gasping in character. Her condition was poor. Prone pressure artificial respiration was administered for

five minutes, with oxygen 95 per cent and carbon dioxide 5 per cent. The inhalator was continued for thirty minutes. The patient was then removed to Morrisania Hospital in a semi-comatose condition. On the day following the poisoning she was removed to Bellevue Hospital, mentally confused and disoriented. Her physical condition seemed good.

On the twelfth day she was admitted to the Manhattan State Hospital from Bellevue Hospital. Mentally the patient was restive, at times excited, but generally apathetic and disinterested. She was completely disoriented, with judgment and insight lacking.

On the fiftieth day a note was made of the immobile facies and somewhat rigid gait, with propulsion.

On the seventy-fifth day, parkinsonism continued.

On the 101st day the patient continued to be uninterested mentally, with poor memory. She was confused, although she was somewhat more oriented, knowing the time and the place. Parkinsonian symptoms continued.

On the 135th day there was no change.

On the 142d day she was paroled to the care of relatives at home.

On the 318th day she mentally had no insight. The neurologic signs were masklike facies and right-sided intentional tremor, the knee jerk reflex was increased on the right and diminished on the left. There was loss of associated movements. The right arm was flexed and held closely pressed against the trunk.

On the 511th day she was discharged, much improved. She appears, however, to have permanent neurologic signs of parkinsonism.

The diagnosis was psychosis due to drugs and other exogenous toxins (illuminating gas) and confusion.

55 Shattuck Street

SCABIES AMONG THE WELL-TO-DO

SOME PRINCIPLES ILLUSTRATED BY THE ELITE

JOHN H. STOKES, M.D.

PHILADELPHIA

My office file contains fifty-three cases of scabies among the better feathered, the silver spooned and the intellectual and professional elect. Of the fifty-three, thirty-seven had seen one or more physicians without relief. Eight had seen "grade A" dermatologists. In five of the eight there had been diagnostic errors. To these I myself contributed one. A total of ten correct diagnoses had been made by forty-nine physicians who saw thirty-seven of the patients. To one of them his family physician made the remark "I would have called it scabies myself if it hadn't been I thought that was a disease no nice people ever had." From twenty-one known sources, sixty-one recognized and an unknown number of unrecognized infestations resulted. Though the subject may seem a bit *infra dig* and on a scale of morbidity rather picaresque in a time of war and rumors of war, there is probably some justification for an analysis and commentary on what has been justly designated as at once the easiest and the most difficult diagnosis in dermatology. Scabies is a disease of herding, promiscuity and travel, of family, school and vacation life. It is thus, of course, like the louse infestation, a plague of armies, tenements and slums. It may with equal force invade a pedigreed school, Camp Wawa Wawa, or the baronial castle on the hill. It may appear in the role of venereal disease capable of being transmitted by bedding with the *fille de joie* and is too often at the site of the penile burrow, the doorman to *Spirochaeta pallida*. The late war, the current human migrations south in winter and north

in summer, the fluidity of present-day populations, all contribute to making scabies an ever present differential consideration, wholly without social boundaries, the possible explanation of the itches of the tycoon, the socialite and the university professor equally with the mechanic's daughter on relief.

Reviewing the outstanding facts of the group of cases thus introduced, it appears that persons of wealth and culture, intellectuals, business and professional men and women and adult members of their families made up two thirds, college and finishing school students, teachers, secretaries, clerks and young children the remainder of my series. A fourth of the cases were recognized within a month, two thirds within three months, two had run more than a year. A case not here included was an offshoot, at a thousand miles distance and a year's standing, of an epidemic involving an entire Florida town, in which the situation had been generally explained as being the result of food poisoning from a carload of spoiled milk chocolate. The victim I encountered was an elderly man, the proprietor of a pair of season hotels of fair standing at opposite ends of the country. I examined him, all unsuspecting, following his frantic appeal in my bedroom at the summer cottage I was visiting. Fortunately nothing happened, though his clothing was scattered over my bed. Of those infestations in this series whose source could be traced, seventeen occurred within the family, ten were incident to travel, six occurred as visitor or visited, two were sexual contacts. Hotels figured three times, one of them a princely hostelry, a swank private hunting lodge was incriminated once, steamers twice, vacations four times. The housekeeper of the hunting lodge had entertained a niece, who had slept for a time in one of the twin beds in the master bedroom. The mistress acquired the infestation, was given glycerophosphates for "nerves" by her internist, told it was gallbladder and change of life by her friends, received calamine lotion by telephone order from me (I plead that I had never seen her, she would not come in, I could not disregard the request, I'll never do it again!) and was thought to have dyshidrosis by another medical adviser. Her husband was found to have a full-blown infestation, classic as to lesions, but whose subjective symptoms he had been too much preoccupied to take seriously. The pet steamship story is of a sportsman visiting in Europe who was informed by his dermatologist abroad that he was suffering from a recurrence of his secondary syphilis (possibly because of his conspicuous urticarial sensitization reaction and the infiltration of the scratch papules). Instead of beginning the recommended course of bismuth he flew for the then record-holding transatlantic liner and burst wildly into my office on the sixth day, a veritable visiting card for the acarus of scabies, which must have distributed his and its compliments broadcast en route. There had been no recurrence of his syphilis, and two weeks accomplished his cure.

THE DIAGNOSIS OF SCABIES

In understanding why the diagnosis of scabies fails, it is clear from this series that the following items are of importance: (1) a low index of suspicion—partly a misuse of social criteria, (2) unfamiliarity with the typical scabetic symptom syndrome, (3) failure to see or recognize the burrow without the use of the lens, (4) failure to distinguish between scabies and its complications and sequelae—i. e., to recognize the underly-

ing trouble, (5) failure to hunt up the contacts for confirmation or illumination, (6) misinterpretation or mishandling of a therapeutic test.

Of thirty-three erroneous diagnoses inferred from course or treatment or known to have been made before the patient's first visit to me, the commonest (and in equal proportions) were "nerves" (the scabetic neurosis), "hives" (the postscabetic or sensitization urticarial reaction), "dermatitis" (scratch plus pyogenic infection) and "physician's quandary," indicated by nondescript internal treatment, including diet, laxatives, antacids (for "acidity") and so on. The full list brings out in addition, as serious contestants, lichen urticatus (chronic papular urticaria of adults), dermatophytosis of the hands with dermatophytid of the body, dermatitis venenata (ivy, primrose), impetigo and pyogenic eczema, and furunculosis. The body and pubic louse infestations must also be included. On these various possibilities the best diagnostic acumen may go astray.

When the diagnosis was finally made, it was found to rest on four observations, in order of importance as follows:

- 1 The burrow, especially on the hands and on the penis
- 2 Nocturnal itching
- 3 Distribution of the eruption
- 4 The identified contact or source

One sign alone made the diagnosis four times, two signs, twenty-one times, three signs nine times, four and five signs six times each, ten cases were rated as "classic," with "everything there" including recognized sequelae.

In order to identify scabies in a doubtful case it is necessary to strip the patient completely. One may find the diagnostic burrow on the instep, especially in infants. Only by having the patient undress completely can one study the geography of the situation and recognize the "map" or distribution of scabies. One must expect of course to see scratch, and in complicated or long-standing cases it may be general. But there is nearly always a concentration of the process, whether scratch or complicating urticarial, pyogenic or eczematoid eruption, about the fingerwebs and wrists, the axillary folds, the nipples (sometimes the chief or only site in women), the belt line and the genitalia. At least two and usually three or more of these regions are involved. As in identifying a faint macular syphilid, one should not stand too close, for distance tends to bring the distribution of the eruption into focus, so to speak. In persons who resist the infestation or whose skins show little general reaction to it, a concentration of urticarial and scratch papules on the buttocks along the anal cleft may arouse suspicion. Nothing is more suggestive of scabies than irregularly shaped dry or scratched papules on the shaft, foreskin and glans of the penis, or the anterior surface of the scrotum, nor can this suspicion be laid to rest by finding the patient to have a positive Wassermann reaction.

The preliminary survey for distribution accomplished, the next step is a search for burrows. Select a thin-skinned region and with a biconvex lens of two diameters or a loupe of up to five diameters magnification inspect the papules for doublets and their connecting burrow, the zigzagness of which varies with their distance apart. At one minuscule mound the *Acarus* enters, and in its top usually is found the yellowish brown ring or pinhead dung heap, quite different when intact from the darker red clot or crust of a scratch papule. At the point finally reached by the adult

female or just short of it the second papule, in reality usually a deep vesicle with a slight pearly translucence, develops. The dung heap is smaller, the vesicular dugout larger. The tunnel in which the eggs are laid joins the two with a directness and purposefulness that perhaps varies with the temperament of the lady and the toughness of the skin. I have seen mild zigzags an inch long on the thin skin of the inner side of the upper arm and dumb-bell-like configurations with a 2 mm straight central bar in the tough skin of the palm. In the more recent burrows, scratch mutilation is less likely and there is more urticarial edema, elevating both papules and burrow. In the older lesions, intraumatized the dung heap papule and burrow are almost flat and recognized chiefly by the pigmented excrement while the dugout retains its edema and translucence for a longer time.

In general it is an unnecessary refinement to attempt to dig out the squatter tenant of the establishment or to shave off tissue to demonstrate the eggs microscopically though both are impressive classroom procedures. To rip up the vesicopapule and the skin just beyond it with a common pin and examine the clinging white speck under low power may occasionally help in a doubtful case but I have not found it necessary in years. In his enthusiasm, the doctor should not show his find to the patient (see acarophobia).

It cannot moreover, be too emphatically stated that the failure to use a lens hampers the diagnosis by papule and burrow hunting at the start. This, if I am not mistaken is the chief source of failure in many seemingly typical cases. Stripped examination and lens search are essentials.

It is not wise to make diagnoses on one papule or on either a straight or a zigzag burrow-like streak, minus one or other of the pair, either dugout or dung-hill for scratch can produce deceptive variations. Whether one burrow with its twin papules can make a diagnosis depends on the experience of the diagnostician. In only four cases did I venture this. Certainly the burrow group is the only lesion on which a diagnosis *solo* may be ventured.

The itching of scabies is surprisingly consistent in its nocturnal character, at least early in the siege. Very late, when acarophobia, sulfur dermatitis, postscabetic urticaria and bath pruritus have all complicated the situation it is more difficult to recognize, but most patients can, even after four months of infestation, testify to the storm of itching that accompanies supposedly the nocturnal parade of the mites in search or excavation of newer and better, or of independent, habitations. Occasional patients do not itch at all, probably because the threshold of itch sensitiveness is like that of pain and varies greatly in individuals. The patient may complain of itching on undressing, or later when becoming warm in bed, the latter, in my observation, much the more distinctive.

Finding a confirmatory human source or contact with scabies in a given case assumes the diagnostic importance still attached by the French to the ritual of confrontation in the diagnosis of chancroid and syphilis. In a doubtful case it is diagnostically important to find a more clear-cut and preferably untreated case from the same source. Therapeutically it is important to ferret out contacts because, through them, untreated, comes relapse. Usually the family provides the best

field for such a search, and infants particularly because of their thin skins and ill directed scratch activities furnish the best fields for the burrow hunt. Distribution in infants, however, is apt to be atypical, because every part of the body including the face and scalp may be affected. Very choice burrows may be found on the sole of the infant foot. A history or an outbreak of impetigo among playmates or in a school room may mask an underlying scabies that will keep going a whole winter, through failure to inspect contacts by a school physician. Comment on the therapeutic test is included under treatment.

THE COMPLICATIONS OF SCABIES

The infection with syphilis of the scabetic patient who has genital lesions, an occurrence of unknown frequency but by no means rare, should always be borne in mind, especially when there have been repeated sexual exposures. Nine burrows transformed into small chancres on a high-priced tobacco buyer's penis by no means touches the limit of this possibility, and dark-field examination of all suspiciously indurated lesions is in order when the circumstances suggest the need for it.

Of all other complications, the following appeared in thirty-three of my fifty-three patients, notwithstanding their good hygiene and better than average intelligence. The sensitization phenomenon postscabetic urticaria developed in nine. Whether due to sensitization to the proteins of the decomposing acari or to their excreta or toxins, there can be no escaping the reality of this disturbance, which begins to appear, at a guess, about a month or six weeks after infestation and is present both during the infestation and for days, weeks or even months after recognizable scabetic lesions have disappeared. The appearance of military hives on the otherwise unaffected skin, the urticarial edema of the scabetic papule and the scratch lesion, and a certain degree of dermatographism all serve to confuse the examiner and to lead even experts to diagnoses of lichen urticatus and food rashes, from which only a painstaking search for burrows and the other distinctive features of a scabetic infestation could save them. The urticarial response is heightened by the nervous reaction to the tormenting itching and loss of sleep, and to the state of mind incident on discovery of the trouble (parasitophobia).

Parasitophobia or acarophobia (seven cases) is a particularly distressing complication of a scabetic infestation, for which physicians themselves may too easily be responsible. The acarophobe can oftenest be identified by his odor, his beset or frantic eye, and his gingerly gestures. In fact, the strong odor of sulfur is *prima facie* evidence either of a phobic misapplication or a badly managed sulfur treatment. The recognition of the dry, chapped or crackly, dusky pink sulfur dermatitis about the folds especially, identifies the trouble. The acarophobe is not necessarily a neurotic, yet his temporary conviction that he is "buggy" may lead to successive unsuccessful "cures" for a nonexistent or previously cured scabies that establishes a vicious mental circle and a round of dermatitic manifestations: lichenification, bath pruritus and dermatographic urticaria, which assumes the proportions of nervous breakdown before the situation is recognized. One grandmother spent \$600 alone in steam and sulfur fumigations of her home, all quite unnecessary, as the result of misdiagnoses and ill considered statements attributed to her physicians, and was finally with diffi-

culty kept out of an asylum herself. In this case the trouble was a senile (*size* soap) pruritus in the first place. A priest, reeking with successive sulfurous ablutions, nearly lost his charge before his plight was recognized. The acarophobic neurosis may assume symbolic or fixational characteristics, the focusing point for personal conflicts and problems, and become unbudgeable without prolonged psychiatric attention.

Every precaution should therefore be taken to set the person to whom a diagnosis of parasitic infestation must be communicated on the right track at the start, by a tactful but authoritative delivery, an absolute assurance of cure, a caution against elements of failure in the treatment technic, which may result in itchy complications mistaken for relapses, and in relapses themselves. Once the way is skilfully paved, only the irresistibly predisposed person develops a significant acarophobia. In highly unstable individuals one is tempted to withhold the diagnosis but this at once runs counter to the necessary instructions for treating the clothing and bedding, and the well meant reticence only creates distrust and defeats itself.

Equal in importance with urticaria (nine cases) is the secondary dermatitis which is to some extent the sequel of treatment in sensitive persons and especially in those who repeatedly "cure" with sulfur and other irritant ointments either with or without explicit direction from their physicians. Here again physicians are remiss in the failure to give explicit warnings and instruction and to refuse prescription refills without reexamination to patients whom they treat for scabies. No prescription containing a skin irritant as universally trouble making as sulfur should be issued without restriction. There is, moreover, a very distinct idiosyncratic reaction to sulfur, and I have seen the wife of a tough-skinned man develop a dermatitis from the sulfur he had used on himself to cure an infestation under my supervision before he returned to share their room, and after he had completed his "cure," with its attendant baths. The effort to cure scabies is a constant compromise between the destruction of the acarids and the excitation of irritative dermatitis, which accounts in part for the popularity of the shorter, less irritative "one day" treatment methods.²

A fourth important complication is what I believe amounts almost to a "sensitization" to pyogenic organisms, resulting in bouts of impetiginous dermatitis, sometimes highly refractory to treatment. These may or may not have an "allergic" factor, as in the scabetic urticaria. They seem also to be particularly frequent in those who are free users of carbohydrate, especially sugar, and of alcohol.

The bath complications (bath itch, bath dermatitis) are confused with the sulfur pictures and usually occur in pure form, so to speak, only in ichthyotic persons, whose congenitally dry, greaseless skins resist irritants less effectively than do the seborrheic, who may actually profit by a sulfurous rubdown or two. Liberal greasing and the grease-based preparations are the best antidote for such difficulties, and preferable thus to the solutions which leave a thin film of sulfur on a drying skin.

It is possible for the clearing up of an extensive scabies to leave an uncovered dermatologic picture ranging from a secondary syphilid to psoriasis or dermatitis herpetiformis. Into this last-mentioned fash-

ionable catch basket of dermatologic classification more than one parasitic infestation would be thrown, were Duhring's disease more familiar to practitioners at large.

TREATMENT OF SCABIES

The treatment of the patients under consideration here was by a uniform and rather old-fashioned method, which I must confess has not been displaced in my estimation by the current scabeticides and one-day cures for which a hurry-up civilization calls. The previous treatment for scabies of the patients whom I observed, and my own failures, brought out some points for emphasis in dealing with this infestation. First, early diagnosis of the scabies greatly diminishes the complications, simplifies the methods of treatment required and improves the results. Cases of less than a month's duration almost never relapsed and were cured in one thirty-six hour course. One of the difficulties in early diagnosis occasionally encountered is a lag in the symptoms of insensitive persons, or persons seemingly resistant, which amounted apparently to as much as a month from the known time of exposure. In fact there would seem almost to be such a thing as an asymptomatic carrier, the fathers of two family groups in my series making no complaints though presenting typical lesions. The relatively late development or complete absence of sensitization urticaria, with its increasing itchiness, may explain the occasional insignificance of itching at the outset, and in some cases of even prolonged infestation of certain insensitive individuals. Because of this carrier possibility, it is well to call in for examination entire families rather than merely the sleeping partner.

Making the perhaps rather large assumption that patients who do not return for observation on the seventh day, as requested, are cured, data were had on twelve relapsing patients who had one or more recurrences, in one case repeatedly for as long as a year. A second reinfestation of an entire family of good social position and good hygiene took place at the end of four years of freedom. Examination of the relapses in relation to complications showed that thirty-two cases might have been regarded as recurrent by the inexperienced and subjected, as some of them were to repeated and undesirable treatment. The twelve bona fide relapses clearly brought out two causes: (1) inadequate instruction of the patient relative to disinfection of clothing and bedding, and (2) an infected but unexamined and untreated contact, most often husband or wife.

I believe it may safely be said that the detail of instructions for personal disinfection, the order not to refill prescriptions without reexamination, follow up to be sure the individual infestation is terminated, precise directions regarding sterilization of fomites, and the detection and effective treatment of all reachable contacts are more important than any individual prescription formula in dealing with scabies. To prescribe a proprietary or give a prescription without all these accompaniments is a direct invitation to complications and relapse.

So far as preparations go, from the tub of Peru balsam and the long handled brush, to the Danish one-day cure, almost anything containing Peru balsam and volatile sulfides, or either sulfur or betanaphthol in a concentration of not less than 10 per cent for the adult, will be effective. The use of an ointment base as a defense against excessive action of the drug and a protection against bath pruritus seems to me desirable,

² With the recently Council accepted pyrethrum ointment (pyrethrum is likewise at times a potent allergen) this series offers no experience for it antedates the preparation.

and repeated application with alternate scrubblings seems to me to insure a result with a single course. The directions that are issued to my patients are given them in writing as follows

ANTISCABETIC DIRECTIONS

First Night Bathe with hot water and soap, soaking well and scrubbing all burrows and pimples open with brush. Rub in ointment over whole body except face and scalp. Special attention to hands, arm pits, waist, nipples, groin and genitals (external).

Next Morning Rub ointment again, without bath. Wear same underwear.

Next Night Rub ointment third time, without bath.

Second Morning Bathe thoroughly, do not apply ointment, powder the body with borated talcum all over. Then put on fresh underwear. Have all bedding changed (sheets, pillow cases).

Send blankets and everyday suit to dry cleaner.

Send linen and underwear to laundry.

Return to the office one week from today.

Use no more ointment unless ordered.

Such particularity may seem to lean over backward, but with it only two relapses occurred in my treatment series, and one of these was due to my failure to detect the contact source at the outset.

A failure to cure with the first course must be rather carefully handled. A week is hardly enough time to determine relapse, so that a longer period may be allowed to pass before a second course is given. It is best to avoid a repetition within two weeks, but it is allowable in one week with tough-skinned or seborrheic patients. Relapse should always be the signal for a thorough inquiry as to the detail with which the regimen was followed, and vigorous reiteration of the procedure, with a renewed search for contact source. A second failure throws the diagnosis seriously into question and raises all the differential problems of urticaria and other complications, and nonscabetic conditions such as interdigital dermatophytosis and dermatophytid. The interdigital vesiculation of the "phyte'-phytid" hand when slight may be confusing even to the expert, but it is impossible to identify doublets plus burrows in it on lens inspection.

A therapeutic test for scabies is a legitimate diagnostic resort after the case has been carefully weighed for ordinary diagnostic evidence. It is inexcusable to plaster every itch with sulfur, of course. The most striking evidence of the success of a therapeutic test is the immediate relief of the intolerable itching on the night of the very first application of the "cure." Failing this sign, treatment is hard to interpret in its objective results within two weeks, and the urticarial complications may by producing apparent "recurrence" seriously confuse the result. Moreover, many diffuse pruritic syndromes including dermatitis herpetiformis are much, though temporarily, relieved by not too much sulfur or betanaphthol. Even the expert will find himself occasionally unable to make a decision short of stopping all forms of treatment and inducing the patient to bring himself and his contacts in repeatedly for the detection of objective evidence.

The urticarial, pyogenic and eczematoid sensitization complications of scabies yield in my experience best to fractional doses of x-rays to the principally involved areas, plus autohemotherapy, and a sharp temporary reduction in carbohydrate and alcohol intake. So uniformly good have my results been that I now treat the patients thus as soon as the diagnosis is made and the complication recognized, coincidently with the prescription of the antiscabetic "cure." The cure of infestations

with even rather pronounced complications can thus be brought within a seven to ten day period. Lacking these appurtenances, starch baths, olive oil and lime water lotions, or ammoniated mercury and boric acid ointments to the worst involved areas, with large doses of calcium salts by mouth, are more slowly effective. A weak ammoniated mercury ointment for two days and the substitution of styra^x and betanaphthol for sulfur may be necessary in infants or children with severe impetiginous complications.

3800 Chestnut Street

THE EFFECT OF ESTROGENIC SUBSTANCE ON HUMAN DIABETES

WILLIAM S. COLLENS, MD
SAMUEL G. SLO-BODKIN, MD
SIDNEY ROSENBLIETT, MD

AND

LOUIS C. BOAS, MD

BROOKLYN

If it is true that the anterior pituitary gland secretes a hormone which has an antagonistic effect on insulin (sometimes considered a diabetogenic hormone) and if it is also true that estrogenic substance has a depressing effect on the activity of the anterior pituitary then it should follow that the administration of estrogenic substance should favorably influence the diabetic state and even cause the chemical characteristics of diabetes to disappear.

A large and varied amount of experimentation has been reported to indicate that the secretion of both the anterior and posterior pituitary bodies have an antagonistic effect on insulin function. The series of articles on the endocrine system that recently appeared in *THE JOURNAL*¹ has so thoroughly covered the literature that we felt it superfluous to include any further bibliography. The method of approach to the study of the antagonistic relationship of pituitary to insulin function may be classified as follows:

1 The injection of anterior pituitary or the existence of hyperfunctioning anterior pituitary bodies in disease states is capable of producing a diabetic picture.

2 The experimental removal of the pituitary gland or the clinical state of hypopituitarism produces a hypoglycemia and an increased sensitivity to insulin.

3 The experimental production of diabetes by pancreatectomy is prevented by the removal of the hypophysis.

4 The posterior pituitary hormones have been suspected of possessing properties that are capable of antagonizing the activity of insulin.

There have been several reports in the literature to show that estrogenic substance has the property of depressing the activity of the anterior pituitary.

Spencer and his associates² have demonstrated that estrogenic substance is capable of depressing both the gonadotropic and the growth principle of the anterior pituitary in castrated rats. Meyer and his co-workers³ have confirmed the inhibitory effect of estrogenic sub-

The authors are indebted to Dr. Henry Joachim, physician in chief, for his cooperation.

From the Diabetic Clinic and Department of Medicine, Israel Zion Hospital and Aurora Institute, Morristown, N. J.

stance on the gonadotropic hormone Leiby⁴ established an increase in weight of the pituitary, thyroid and adrenal after the administration of theelol to mature albino rats. In another paper⁵ he reported that these glands show a marked increase in weight after a combination of anterior pituitary-like principle from the urine of pregnancy and theelin is given. These observations are decidedly contradictory to the determinations of Burch and Cunningham,⁶ who found that the gonadotropic function of the pituitary is increased after the administration of placental extract. An important contribution which presented a practical clinical bearing in the treatment of diabetes came from Barnes and Regan.⁷ These authors administered 200 rat units of estrogenic substance⁸ to dogs for a period of three weeks before performing a pancreatectomy and continued the administration of the substance for a period of three weeks after the operation. They showed that their animals did not develop a pronounced form of diabetes until after the substance was discontinued. They also removed the pancreas of dogs without previous preparation with estrogenic substance, permitting the state of total diabetes to develop, and then were able to reduce the severity of the disease by giving the substance. They concluded from their experiments that estrogenic substance, by suppressing the activity of the anterior pituitary lobe, favorably influences the experimental diabetic state in dogs and suggested its possible clinical application to human diabetes, warning, however, of the danger of adrenal cortical suppression.

These studies have recently been confirmed by the experimental investigations of Nelson and Overholser,⁹ who were able to prevent the development of glycosuria in pancreatectomized rhesus monkeys by the daily administration of posterior pituitary extract. They also found that the diabetic blood sugar was

These reports represent excellent experimental evidence that the pituitary possesses a principle which is capable of antagonizing insulin and that estrogenic substance has a depressing effect on anterior pituitary function.

This paper is concerned with a report of investigations intended to determine the possible application of these observations to the treatment of human diabetes.

Chart 2—Course of diabetes in case 2

REPORT OF CASES

Seven patients with diabetes of varying degrees of severity were selected for this study. Estrogenic substance was employed in daily doses varying between 100 and 400 rat units. Adequate control periods were established in each case and the estrogenic substance was administered continuously for periods up to one month. The diabetic tolerance was established during the previous control period, the experimental period and the postexperimental period. In some cases the insulin was discontinued and estrogenic substance substituted. The details of each experiment will be found in the reports of the following cases and in the accompanying charts.

CASE 1—J. K., a man, aged 59, Jewish, admitted to the Israel Zion Hospital, Sept 23, 1933, had developed diabetes at 48 years of age. He had been under an irregular form of diabetic management during this entire period. On admission he showed nothing significant in the physical examination except that he was slightly underweight. The fasting blood sugar was 340 mg per hundred cubic centimeters and he was excreting 32 Gm of sugar in twenty-four hours. He weighed 135 pounds (61 Kg). He was placed on a diet containing carbohydrate 125 Gm, protein 60 Gm, fat 90 Gm, totaling 1,550 calories, with an available dextrose content of 170 Gm. He was kept on the same diet during the entire experimental period. It will be observed from chart 1 that he excreted a fairly constant amount of sugar during the control period of four days and that his fasting blood sugar was constantly high. He was then given daily 100 rat units of estrogenic substance subcutaneously for a period of eight days during which he still excreted sugar ranging between 10 and 40 Gm. It was necessary to stop the investigation at this point because of the development of much pain at the site of injection, to which the patient objected. He was then immediately placed on 10 units of insulin three times a day and within three days the urine became sugar free and remained so. Blood sugars, however, remained constantly high.

CASE 2—M. P., a woman, aged 59, Jewish, admitted to the hospital Oct 3, 1933, had a partial thyroidectomy fourteen years before for hyperthyroidism. Sixteen years following the onset of the menopause manifestations of diabetes appeared. She had received dietetic treatment during the entire period.

Chart 1—Course of diabetes in case 1

lowered after estrogenic substance was given and concluded that the estrogenic substance depresses the diabetogenic hormone of the anterior pituitary.

of the diabetes and had taken insulin for one year prior to her admission. On admission to the hospital she showed manifestations of hyperthyroidism, diabetes and hypertension. She appeared chronically ill and was wasted. She had a nodular enlargement of the right lobe of the thyroid the size of an apricot. The heart was fibrillating, the liver was three finger-breadths below the costal margin, congestive rales were present

Chart 3—Course of diabetes in case 3

at the bases of the lungs and there was a slight edema of the abdominal wall, as well as a pretibial edema. The diagnosis was that of a toxic thyroid adenoma, essential hypertension, coronary sclerosis, auricular fibrillation, myofibrosis cordis, cardiac decompensation and diabetes mellitus with ketonuria. The basal metabolic rate was plus 20 per cent. The blood pressure was 180 systolic, 100 diastolic and she weighed 102 pounds (46 Kg) on admission. Urine showed 2 per cent sugar and 3 plus acetone in a casual specimen. Fasting blood sugar was 253 mg per hundred cubic centimeters. She was placed on a diet containing carbohydrate 175 Gm, protein 75 Gm and fat 125 Gm with 25 units of insulin three times a day. She was also given 400 rat units of estrogenic substance subcutaneously each day. The urinary excretion of sugar continued between 12 and 28 Gm in spite of the fact that the insulin was gradually increased to a point at which she received

Chart 4—Course of diabetes in case 4

120 units daily. At the end of nine days the estrogenic substance was stopped, following which the urinary sugar promptly disappeared. Even when insulin was reduced to 60 units daily four days after estrogenic substance was stopped, the urine still remained free from sugar. This improvement occurred in spite of the fact that the available dextrose was increased from 210 to 256 Gm.

This experiment appears to indicate clearly that the estrogenic substance not only did not favorably influence the diabetic state but interfered with the recovery of the patient, which occurred promptly after the cessation of the use of the estrogenic substance.

CASE 3—I W, a woman, aged 69, Jewish, had been known to have diabetes for eighteen years. The diabetes developed after the menopause. For two years after her admission she had been attending the diabetic clinic, during which time her tolerance was maintained rather constantly on a diet containing 200 Gm of available dextrose, with 25 units of insulin daily. She was admitted to the hospital Sept 30, 1933, for the purpose of being studied for the effect of estrogenic substance under adequate control conditions. She was given a diet of carbohydrate 125 Gm, protein 60 Gm and fat 100 Gm, with 15 units of insulin in the morning and 10 units of insulin at night. Insulin was stopped on the third day, as a result of which she began to excrete from 19 to 22 Gm of sugar in the urine each twenty-four hours. Beginning with the fifth day she was given 200 rat units of estrogenic substance daily by hypodermic injection and within twenty-four hours the urinary excretion

Chart 5—Course of diabetes in case 5

of sugar rose to 50 Gm and showed acetone and diacetic acid. On the seventh day she was put back on 30 units of insulin and the estrogenic substance was still continued. Glycosuria did not disappear until the estrogenic substance was stopped and the insulin increased to 60 units daily.

This case clearly shows that the estrogenic substance, after insulin was suspended, had absolutely no effect on retarding the severe break in sugar tolerance with a rapid development of ketonuria, which could be controlled only by the subsequent administration of insulin.

CASE 4—B B, a woman, aged 54, Jewish, was found to have diabetes in 1929 by a routine examination at the time when the patient had an appendectomy performed. The menses ceased after the operation. Under observation at the clinic, Aug 20, 1932, she complained of weight loss, blurring of vision, pruritus vulvae and weakness. Examination disclosed manifestations of vascular sclerosis, hemorrhages in the eyegrounds and a hypertensive heart. The blood pressure was 194 systolic, 100 diastolic. She was treated with diet and insulin. Her diet contained 175 Gm of available dextrose and 20 units of insulin a day for one month during which time the clinical symptoms improved considerably. Then she voluntarily stopped using insulin. Chart 4 discloses the course of the patient's diabetes for one year prior to the experiment with estrogenic substance. Oct 26, 1933, she was started on 200 rat units of estrogenic substance oral daily for twenty-three consecutive days.

Although the subjective menopausal symptoms improved, it will be seen from chart 4 that there was no change in her diabetic state.

CASE 5—C W, a woman, aged 42, Jewish, who came under observation June 2, 1929, complained of the cardinal symptoms of diabetes of four months' duration. Her symptoms were polydipsia, polyphagia, polyuria, progressive asthenia, oral dryness and pruritus vulvae, she also had frequent attacks of flushes and sweats, in spite of the fact that the catamenia had been regular. The patient had been maintained on a diet containing variable quantities of available dextrose ranging from 150 to 190 Gm. She had refused to take insulin at any time and had been continuously on dietetic management and always excreted between 15 and 40 Gm of sugar daily. She was never considered a very cooperative patient.

Chart 5 shows the record of her diet and urinary excretion for a period of six months before the experiment with estrogenic substance was performed. Oct 17, 1933 she was started on 200 rat units of oral estrogenic substance daily, which was continued to November 14, a period of approximately four weeks. Her chart also discloses the character of her urinary excretion of sugar for six months after the experiment was stopped.

It will be observed that there is no appreciable difference between the control period, the experimental period and the postexperimental period.

CASE 6—L K, a woman, aged 35, Jewish, came under observation at the clinic with a history of diabetes of two years' duration. She was found to have 10 per cent sugar in the urine, with acetone. She was adequately controlled with a diet of carbohydrate 160 Gm, protein 60 Gm, fat 75 Gm and 40 units of insulin daily. Oct 12, 1933, she was given 200 rat units of estrogenic substance subcutaneously, at which time she was excreting traces of sugar in the urine. She was given estrogenic substance for one month while continuing the same dose of insulin. The urine persisted in showing the same traces of sugar and the blood sugar remained at a level fluctuating between 220 and 280 mg per hundred cubic centimeters.

There was no evidence in this case that diabetes was influenced by estrogenic substance.

CASE 7—M B, a woman, aged 57, Jewish, admitted to the hospital Sept 25, 1933, had had diabetes fourteen years, the onset following the menopause. Her initial complaint was pruritus vulvae and her weight at that time was 280 pounds (127 Kg). She had received dietary treatment and had lost considerable weight. She was admitted to the hospital because of an attack of multiple furunculosis of the scalp. Physical

maintained during the entire experimental period. Three days after admission she was given 200 rat units of estrogenic substance subcutaneously daily for nine consecutive days. Although her blood sugar dropped to 260 mg per hundred cubic centimeters, the urinary excretion continued to rise progressively to 40 Gm a day. The patient was then put on 35 units of insulin daily but she left the hospital against advice before an

Chart 7—Course of diabetes in case 7

opportunity could be obtained to compare the effect of insulin with that of estrogenic substance. There was no evidence that the estrogenic substance had any effect on the diabetic state.

COMMENT

The observations presented here appear to indicate that estrogenic substance has absolutely no effect on the course of human diabetes. The cases in which insulin was stopped and estrogenic substance substituted showed a rapid break in sugar tolerance, sufficient to precipitate the development of a ketonuria. In case 2, which was so severe that we were afraid to suspend the use of insulin during the experiment with estrogenic substance, so severe a diabetic state seems to have developed during the experimental period that we found it necessary to increase the insulin dosage from 75 units to 120 units daily in order to control it. Another interesting feature in this case is that rapid desugarization could be effected as soon as the estrogenic substance was stopped, and even reducing the insulin to the preestrogenic substance period resulted in better control. One may safely say that at the time this patient received daily subcutaneous injections of 400 rat units of estrogenic substance the diabetic state was more severe.

Since our clinical experiments are at such marked variance with the observations reported in experimentally produced diabetes in animals by pancreatectomy, we can only say that human diabetes is pathogenically not similar to experimental diabetes in animals. Although the chemical phenomena of disturbed dextrose oxidation and synthesis are similar in the two instances, it does not necessarily follow that the human diabetic state results only from a nonfunctioning pancreas. And by the same token, what appears to alter the picture of the pancreatectomized animal cannot be logically applied to the human diabetic patient.

CONCLUSION

1 It appears from the literature that anterior pituitary hormone antagonizes insulin, that estrogenic substance suppresses anterior pituitary function, and that

Chart 6—Course of diabetes in case 6

examination disclosed, besides the furuncles, manifestations of arteriosclerotic heart disease moderately decompensated as indicated by moist rales at both bases, a palpable liver and a moderate amount of pitting edema of both legs. The blood pressure was 180 systolic, 110 diastolic and the fasting blood sugar 355 mg per hundred cubic centimeters. She was excreting 12 Gm of sugar in the urine. She weighed 162 pounds (73.5 Kg). She was placed on a diet of carbohydrate 150 Gm, protein 60 Gm and fat 110 Gm without insulin. This diet was

NEUROFIBROMATOSIS

THE EFFECT OF PREGNANCY ON THE SKIN MANIFESTATIONS

JOHN C SHARPE, MD

AND

RICHARD H YOUNG, MD

OMAHA

A survey of the literature reveals only a few examples of the effect of pregnancy on neurofibromatosis. Sutton¹ reported the case of a woman, aged 38, who noted pedunculated tumors of the skin, which appeared during her first pregnancy and disappeared completely following delivery. The tumors reappeared during a second pregnancy and persisted. The microscopic study of the skin lesions revealed them to be neurofibroma of von Recklinghausen. Recently, cases of preexisting neurofibromatosis that were made worse with the occurrence of pregnancy but showed a remission following delivery are reported by Kushner,² Nishizaki,³ and Hursh.⁴ Other accounts in the literature⁴ describe easily confused lesions termed "pigmented warts" and "fibroma molluscum gravidarum," which appear during pregnancy and disappear following delivery.

During the past three years we have examined fifteen cases of the various types of Recklinghausen's neurofibromatosis. In this group we were impressed by the fact that in four cases the course of the disease was definitely influenced by pregnancy. The changes with pregnancy were so dramatic and the effect so distressing that a report seemed warranted.

REPORT OF CASES

CASE 1—Development of skin pigmentation and tumors during the latter half of the first pregnancy with no change after delivery or with second pregnancy

J A, a white woman, aged 34, married, a housewife, entered the University of Nebraska Dispensary, June 11, 1935, complaining of a sharp, paroxysmal pain in the left upper part of the chest and back, which had been present for two weeks. On examination, interest was at once aroused because of the presence of a moderate number of irregular, café au lait pigmented spots in the skin of the trunk. In addition there were about twenty painless, asymmetrical skin and subcutaneous tumor growths of the lower part of the back and the abdomen. There was a slight scoliosis. Roentgenograms of the chest revealed a mass, which was considered a neurofibroma involving the intervertebral foramina of the third and fourth dorsal

vertebrae and probably accounting for the pain. Both the patient and her husband stated quite definitely that there had been no skin pigmentation or tumors prior to her pregnancy. They observed their appearance and progression during the latter half of her first pregnancy. Following a normal delivery, the skin manifestations persisted. A second pregnancy seven years later caused no apparent change in either the skin pigmentation or the size and number of the nodules. There had been one miscarriage five years before. At present, her first child has a clear skin, but her 7 year old son has a number of scattered, irregular brownish pigmented spots on his back and abdomen which have been present since infancy. The family history was interesting in that the patient's mother had both skin tumors and pigmentation and died of a sarcoma (?) of the left femur. The patient's two brothers have skin tumors, and one of their daughters is known to be deeply pigmented.

CASE 2—Development of multiple skin tumors and pigmented areas during first pregnancy, with an increase in these manifestations during each of seven successive pregnancies

E C, a white woman, aged 56, a widow, entered the University Hospital, Jan 1, 1935, because of a constant pain in the left thigh for the preceding six months. Examination disclosed multiple painless skin and subcutaneous nodules, pigmented and nonpigmented, distributed mostly on the trunk, with a few on the face and extremities. The skin of the abdomen and neck was irregularly pigmented a brownish black. Before her marriage, the patient's skin was clear except for an occasional freckle on the face and forearms, and one small skin tumor below the left knee. During her first pregnancy, at the age of 19, multiple skin tumors and pigmented spots appeared on her abdomen and back. Following delivery the skin nodules ceased to increase in size and number, but during each of the seven successive pregnancies the same phenomenon repeated itself. Except for three miscarriages there were no other complications of pregnancy. Five of her children are living and well, one daughter, aged 24, is moderately pigmented and has a few subcutaneous nodules. The patient's father was heavily "freckled", the mother, four brothers and five sisters all have clear skins.

CASE 3—Pigmentation prior to pregnancy, with appearance of skin tumors during first pregnancy and resumption of activity with each of six pregnancies

M E, a woman, aged 38, married, Italian, a housewife, entered the University Hospital, Aug 4, 1932 in the active stages of labor in her sixth pregnancy. On examination she showed a deeply pigmented skin, brownish black, most marked on the neck and upper extremities. In addition there were many painless skin and subcutaneous nodules of varying size on the abdomen, chest, back and extremities. Though she had had a few pigmented spots on her back since early infancy, the skin tumors had not appeared until the latter half of her first pregnancy. The nodules and pigmentation ceased to advance following delivery, but resumed their activity with each of the following pregnancies. There had been one miscarriage. Because of the presence of a severe scoliosis, extra precautions were taken with each delivery, but no complications had developed. Two of the patient's daughters, aged 3 and 9, have several pigmented café au lait spots on the trunk and extremities, and, in addition, one has a small subcutaneous nodule covered with hair. The patient's mother had had both skin tumors and pigmentation, but her one sister and brother have clear skins.

CASE 4—Generalized pigmentation and formation of skin tumors during first pregnancy with exacerbation of these features in seven successive pregnancies

M J, a white woman, aged 34, married, housewife, entered the University Hospital, Jan 17 1935 with the chief complaints of pain and swelling in the right inguinal region of several weeks' duration. On examination, she showed an extensive, dark irregular freckling over the body, with numerous soft, small, painless subcutaneous nodules distributed mostly over the trunk and arms. Since infancy the patient had had a flat brown spot, 3 inches (7.6 cm) in diameter, in the skin of the right inguinal region. It had several tufts of hair growing from it. Generalized pigmentation and skin tumors appeared and per-

sisted with each of seven pregnancies. There was no difficulty in her deliveries, there had been two miscarriages. The large tumor in the inguinal region had increased noticeably in size with each of the last three pregnancies, and for some unknown reason during the few weeks preceding admission. Of the five children living and well, three show large brown areas of skin pigmentation but no nodules. The patient's mother and father have a clear skin, three sisters all show a deep "freckling" on their faces and necks.

COMMENT

In the report of these four cases, one is immediately impressed with the very definite, detrimental effect of pregnancy on the course of Recklinghausen's neurofibromatosis. Three of the patients had noted café au lait pigmentation of the skin since early childhood (forme fruste), the fourth had had a clear skin until her first pregnancy. In only one case had a solitary subcutaneous nodule developed before pregnancy. In all the patients the occurrence of the first pregnancy gave rise to the appearance of numerous skin and subcutaneous tumors. Histologic study classified them as neurofibromas. In addition, numerous areas of brownish pigmentation occurred that were confined chiefly to the trunk. In all instances, delivery seemed to cause an arrest in the growth and multiplicity of the skin tumors. However, with each subsequent pregnancy the same phenomena occurred. Two patients had had one miscarriage, one had had two miscarriages and the fourth had had three miscarriages. Delivery was normal in each case. Two patients gave a history of irregular menstrual periods and dysmenorrhea. The family history of the four cases reveals that one or both parents had manifestations of the disease. It is also pertinent that each of the four patients have one or more children with the incomplete form of the disease. Three of the four patients are yet in the child bearing age group and are greatly disturbed concerning the possibility of additional pregnancies. In three of the four cases there has been such advancement of the disease that the tumors by pressure on or direct extension into the nerves have caused pain. Besides the production of pain in these three cases the cosmetic effect, the possibility of bone or central nervous system involvement and the chance of ulceration or malignant degeneration are all potent reasons for avoiding additional pregnancies. This naturally leads to the question of sterilization of the patients. In justification, young women with the "incomplete" form of the disease should be warned about the harmful effects of pregnancy.

In the male cases, except for the influence of puberty, there is no comparable phenomenon occurring in their life that increased the skin manifestations. Yet the disease may be just as far advanced and have just as many complications as the type we describe. The factor in pregnancy that causes the lighting up of what might be called the dormant, "incomplete" form of the disease is unknown. We are not yet prepared to theorize on the cause of the disease but the association of an endocrinopathy, very possibly pituitary, in combination with a developmental anomaly is naturally an inviting explanation. The association of acromegaly and neurofibromatosis has been reported several different times.

SUMMARY

1 Various combinations of skin nodules and pigmentation may occur before, during and after pregnancy.

2 The exacerbation of the disease by pregnancy increased the possibility of bone or central nervous

system involvement, the chance of ulceration or malignant degeneration, and the incidence of pain.

3 In four cases Recklinghausen's neurofibromatosis was made definitely worse with pregnancy, as shown by an increase in skin pigmentation, tumor growth, and the development of pain.

4 There were no complications of delivery as a result of the disease.

5 It would seem advisable to prevent the occurrence of pregnancy in those women with either the "incomplete" or complete form of the disease.

REDUCTION IN COLLOIDAL OSMOTIC
PRESSURE OF BLOOD SERUM
AFTER SALT INGESTION

HAROLD C. TORBERT, M.D.
AND
GARNETT CHENEY, M.D.
SAN FRANCISCO

During the course of study of effects of high sodium chloride intake on the blood, the osmotic pressure of plasma protein was measured before, during and after

Decrease in colloidal osmotic pressure and serum protein concentration as a result of ingestion of 5 Gm. of sodium chloride daily for two days in subject D. R.

two periods of one day each and two periods of nine days each of high salt ingestion, the sodium chloride intake of the subjects ranging from 20 to 60 Gm. daily. In all the experiments there was a fall in the colloidal osmotic pressure per gram of protein during the period of high salt intake, but owing to technical difficulties with the method we were not satisfied with these observations. Two shorter experiments in which the subjects ingested 50 Gm. of sodium chloride daily for two days have now been completed, membranes and technic being used that yield correct values with normal serums. Puffiness of the eyelids and edema of the ankles were noted in each period of salt feeding. The data for these experiments are given in the table and

the chart. There was no change in the albumin-globulin ratio during salt administration. No control experiments with other electrolytes have been completed.

COMMENT

The fall in osmotic pressure of plasma colloids during periods of forced salt ingestion is greater than can be accounted for by change in plasma protein concentration or in albumin-globulin ratio. The practical implications are obvious. It has been known for a long time that restriction of salt in edematous patients with nephritis with low plasma protein may be followed by relief of edema and vice versa. No observations are

on record, however, of colloidal pressure studies under these conditions. In view of the present experiments a reasonable explanation is forthcoming, which explains edema without assuming two entirely different mecha-

RECENT ADVANCES IN THE SURGICAL TREATMENT OF CHRONIC DUODENAL ULCERS

RICHARD LEWISOHN, M.D.
NEW YORK

The proper surgical management of gastroduodenal ulcers is one of the most controversial subjects as judged by perusing the most recent literature. Different procedures for the cure of peptic ulcers have been advocated since Wolfer introduced gastro-enterostomy for the alleviation of pyloric obstruction. In spite of the period of five decades that has elapsed since his important contribution, opinions have differed widely among surgeons as to the best form of treatment.

For the sake of brevity I shall refrain from entering into a historical review of this subject. As to the advances that have been made during the last fifty years in the treatment of gastric ulcers, one need mention only the terms gastro-enterostomy, local excision, sleeve resection and partial or subtotal gastrectomy to indicate the progress in this field.

In the surgical treatment of duodenal ulcers, progress has been much slower. The palliative methods (gastro-enterostomy with and without pyloric exclusion or with excision of an ulcer on the anterior wall of the duodenum and the different forms of pyloroplasties) seemed to be well entrenched until Haberer¹ introduced the more radical method of partial gastrectomy as the method of choice for duodenal ulcers.

It should be emphasized that it is absolutely impossible to make one method fit every condition. No experienced gastric surgeon will claim that partial or subtotal gastrectomy is applicable to every case of peptic ulcer.

The issue has been clouded by overenthusiasm for the radical methods on the one hand and by undue stress on the dangers of gastric resection by the opponents of this method on the other. It has been asserted—and undoubtedly with a great deal of justification—that the substitution of gastric resection for gastro-enterostomy by the general surgeon would raise the mortality to a prohibitive level.

Radical gastric surgery will never be in the realm of the general surgeon with a limited experience in this special field. In order to obtain good results an organization is required, consisting not only of a surgeon with extensive experience in this special field of surgery but of a specially trained intern and nursing staff. Close observation of the patient in the postoperative course is one of the essentials to success in this field of surgery. It is one of the unavoidable results of further progress in new fields of surgery that special groups are formed among surgeons. Nobody will deny today the justification for specialization in thyroid, brain or genito-urinary surgery, to mention just a few that have been formed into special groups within recent years. Though the surgeon becomes narrower in his training, the patient benefits by this specialization.

I² have pointed out in a previous paper that it would be impossible to subject every case of gastroduodenal ulcer to a partial or subtotal gastrectomy without incurring a very high mortality. Anybody who has studied carefully in the dissecting room the anatomic relations and the close proximity of a deep duodenal ulcer to the common duct or of a high gastric ulcer in juxtaposition to the cardia will concede that ulcers in these locations cannot be attacked radically without a mortality of at least 20 per cent.

If the majority of ulcers were found in these locations, even the most skilful surgeon would find his mortality figures so high that he would soon abandon radical measures.

It is undoubtedly fortunate for both the surgeon and the patient that ulcers are rarely found in these two locations, probably not in more than about 5 per cent of the cases. The vast majority of ulcers are located in the distal half of the stomach and the first part of the duodenum, the so-called ulcer bearing area, and can be removed radically without undue risk to the patient.

If this small group of nonresectable ulcers is excluded from radical resection, partial and subtotal gastrectomy step out of the realm of hazardous surgery and become perfectly safe procedures, with a mortality not higher than gastro-enterostomy and with a percentage of permanent cures infinitely higher than that following the latter method.

It requires considerable experience to decide, after the affected region has been explored, whether an ulcer should be dealt with radically. The surgeon must keep in mind that once the ulcer has been freed from the pancreas (and about 50 per cent are located on the posterior duodenal wall) he cannot retrace his steps but must proceed with radical resection. In other words, he must visualize the anatomic relations before he begins the resection. He must know whether he will

be able to effect a safe closure of the duodenum or whether secondary inflammatory changes are so extensive that the sutures cannot be carried through healthy tissues with the grave risk of a duodenal fistula, with possibly a lethal outcome.

However, even in the small group of cases in which radical removal is not possible, the patient need not be subjected to a gastro-enterostomy. Finsterer's so-called *resektion zur ausschaltung* may be safely applied in these cases. The name is not a happy selection. I think that the term Finsterer's prepyloric or postpyloric gastric resection would have been more appropriate. Finsterer's operation leaves the duodenal ulcer in place and carries the line of dissection either just in front of or just beyond the pylorus and insures complete sidetracking of the food. By putting the ulcer at complete rest, secondary healing of the ulcer is supposed to be effected in a reasonable time. In order to establish a marked reduction in the acidity, the proximal line of dissection should be carried as high up as possible on the lesser curvature of the stomach. While the results after a Finsterer operation are often not as good as those following a resection, this method is far superior to a gastro-enterostomy.

Gastro-enterostomy for nonobstructed duodenal ulcer is a badly conceived operation. It should be used only in the small group of cases in which diseases of heart and blood vessels, lungs or kidneys contraindicate any major operation. It may still have its place in the cases of marked obstruction due to a healed ulcer. But I feel that even in this group of cases its value is limited and that resection should be attempted whenever possible. A temporarily healed ulcer may become reactivated at a later period and cause recurrent symptoms. Instead of being praised as the "method of choice," gastro-enterostomy should be denoted to a "method of expediency" in the treatment of duodenal ulcers when for very sound reasons the better operative methods are not applicable.

The gradually increasing unpopularity of gastro-enterostomy is based not only on the frequency with which gastrojejunal or jejunal ulceration follows this procedure but on the persistence of symptoms, even in the absence of secondary ulceration. The patient is not improved, the hyperacidity persists, the preoperative pylorospasm still gives him symptoms. It can be demonstrated easily by giving an animal thionin blue that a gastro-enterostomy does not change the route for the passage of food which still leaves the stomach by way of the pylorus and duodenum and does not select the stomach, which presents not only a useless but a very dangerous and vulnerable *locus minoris resistentiae*.

Statistics as to the frequency of gastrojejunal ulcers vary widely. They are variously estimated to be below 5 per cent and over 30 per cent. It is perfectly clear that statistics cannot be compared unless they are computed on exactly the same basis. Many statistics include only the cases in which operation has been performed and leave out of account those in which reoperation has not been done although they may possess all the clinical symptoms of recurrent ulceration. The high incidence of gastrojejunal and jejunal ulcers as reported by me³ is to be accounted for by the fact that I included cases in which reoperation was done and cases in which operation was not done and in which the diagnosis was unequivocal. Otherwise I would have had 18 per cent instead of 34 per cent.

When this report was published ten years ago the results were criticized as unduly high not only in this country but in Europe. Since then, however, other authors have published similar figures, in some instances even reporting a considerably higher incidence of this most dreadful postgastro-enterostomy complication than I did. For instance, Enderlen and Zukschwerdt⁴ found 51 per cent of gastrojejunal ulcers among forty-two patients who had a previous suture of an acute perforation with gastro-enterostomy.

I feel that my estimate was rather conservative. Just as in primary ulcers, all shades of secondary gastrojejunal ulcerations are encountered. These vary from the mild forms to those with very severe manifestations. Hinton and Church⁵ have shown that gastrojejunal ulcers encountered at reoperation may present negative roentgen manifestations. Unless one becomes "gastrojejunal ulcer minded," many of the cases of recurrence will be overlooked. One must face the problem with an open mind and not be afraid to acknowledge the failure of a gastro-enterostomy to oneself and to one's patients. If surgeons would scrutinize their results in this frame of mind, the percentage of gastrojejunal and jejunal ulcers as reported by them would probably rise to the neighborhood of 50 per cent.

If an operation for gastrojejunal ulcer would represent a comparatively small operative risk, the major operation of gastric resection might be safely deferred, until this complication arises. However, subtotal gastrectomy for gastrojejunal or jejunal ulcer is accompanied by a mortality of at least 20 per cent. In the presence of a gastrojejunocolic fistula the mortality is much higher. It is not fair to any patient who may have a good life expectancy in spite of his duodenal ulcer to perform a gastro-enterostomy which later on may require a secondary operation with such an inherent high mortality. Gastric resection for gastrojejunal ulcer is one of the most formidable operations in the upper part of the abdomen. Therefore, it is the duty of every surgeon to use surgical methods that minimize the possibility of gastrojejunal ulceration.

If gastric resection is to replace gastro-enterostomy in the surgical treatment of duodenal ulcer it must answer two requirements: the mortality must not be higher than that of gastro-enterostomy and the number of recurrent ulcers must be much lower than those following the latter operation.

MORTALITY

The opponents of gastric resection have laid undue stress on the inherent high mortality of this operation. Undoubtedly some mortality statistics of 10 per cent and over have kept surgeons from adopting this method. However, other statistics show much better results. Bohman's⁶ mortality of 3.1 per cent, Koennecke's⁷ of 1.5 per cent and my mortality of 2 per cent for partial and subtotal gastrectomy in primary gastroduodenal ulcers compare favorably with the postgastro-enterostomy mortality, which is usually reported as between 2 and 3 per cent. Haberer⁸ has reported 100 consecutive gastric resections for gastroduodenal ulcers without a death. It is immaterial for the operative

results whether the first or the second Billroth method is used. For instance, Bohmansson and Haberer use the first Billroth method or their modifications almost exclusively, Koennecke employs the first Billroth method at the rate of 2 to 1, and I prefer the second Billroth operation. It is not the place here to discuss the comparative advantages and disadvantages of these two methods. The surgeon should apply the method that gives him the best immediate and late results.

SECONDARY ULCERATION

When I reported the high incidence of gastrojejunal ulcers (34 per cent) following gastro-enterostomies for duodenal ulcers, performed in the surgical service of Dr. A. A. Berg, the argument was advanced that later statistics from this service might show that partial gastrectomy would not reduce these high figures to a considerable degree. This question could not be answered until sufficient time had elapsed for a proper comparison of these two methods. I have always held that at least an interval of five years is required before fairly definite conclusions about the frequency of gastrojejunal ulcers can be drawn. I am now able to prove my contention that the major operation of partial gastrectomy will reduce considerably the number of gastrojejunal ulcers. Mage presented last year before the Medical Fortnightly of the New York Academy of Medicine a five year follow up of the results of

Comparison of Follow-Up Results in Gastro-Enterostomy and Partial Gastrectomy for Duodenal Ulcers

	Cases	Operation Between	Reexamination in	Gastro-jejunal Ulcer	Proved by Reoperation
Gastro-enterostomy	68	1915 and 1920	1924	23 cases (34%)	12 cases (18%)
Partial gastrectomy	82	1924 and 1929	1933	6 cases (7%)	1 case (1.2%)

partial gastrectomy performed by Dr. Berg and his associates between 1924 and 1929. A comparison of these two series, given in the accompanying table, shows that the frequency of gastrojejunal ulcers has been reduced from 34 per cent to 7 per cent. In both series the follow up after five years represented about 50 per cent of the material in which operation was performed.

The vast majority of statistics figure the incidence of gastrojejunal ulcers on the basis of reoperations. If one follows this procedure—though I do not approve of this method—the reduction is even more striking, namely, from 18 per cent to 1 per cent.

The value of these statistics lies in the fact that they were computed on the same basis. The same group of men used identical methods (careful personal examination of the patients, investigations by roentgenography and test meals) in the two series. A comparison of statistics published from different clinics relating to the follow-up results after gastro-enterostomy and gastric resection is of little value, as they are arrived at on a different basis.

TERMINOLOGY

A few words about terminology. Gastric resection means the removal of the distal half of the stomach (partial gastrectomy) or more (subtotal gastrectomy). Pylorotomies or partial antrumectomies should not be called gastric resections. The latter operations, though connected with a mortality as high as that following a properly executed gastric resection, have an incidence of gastrojejunal ulcers not lower than that following

gastro-enterostomy. Pylorotomy and partial antrumectomy fail to remove the ulcer-bearing area and to reduce the gastric acidity. It is perfectly evident, therefore, that recurrences are apt to follow these operations. The discussion is by no means purely academic. A number of authors have reported gastrojejunal ulcers following these incomplete operations. Instead of blaming the incomplete operation for the recurrence, they have called it a failure of partial gastrectomy. Only a sufficiently wide resection offers a chance for a permanent cure of the patient. A similar circumstance surrounds the surgery in exophthalmic goiter. The best results in operations on the thyroid gland are obtained when only small amounts of thyroid tissue are left behind. If recurrences occur after an incomplete thyroidectomy, the surgeon is justly blamed and not the method. In the same manner gastrojejunal ulcers, after pylorotomies, redound to the discredit of the surgeon rather than to the method.

COMMENT

Sebening⁹ has raised an interesting point by referring to the difference in the types of gastroduodenal ulcer encountered in central Europe and in this country. He has tried to explain the reason for the popularity of gastric resection in Germany and Austria as opposed to the popularity of gastro-enterostomy in North America on the basis that ulcers on the continent of Europe are much more severe and extensive than in the United States. I cannot agree with this statement. Frequent visits to European clinics have convinced me that ulcers are identical on the two continents and that all types of ulcers are found on both sides of the Atlantic. One has frankly to face the issue of whether gastro-enterostomy or gastric resection is the preferable surgical procedure. The size of the ulcer is of minor importance, as gastrojejunal ulcers follow small duodenal ulcers just as often as they do large ulcers.

The opponents of gastric resection for duodenal ulcer have laid considerable stress on the fact that a postoperative anacidity is established in not more than about 66 per cent of the cases. The argument has been advanced that it is unjustifiable to subject patients to the major operation of partial gastrectomy if about 34 per cent continue to have free hydrochloric acid. This contention fails to consider two important points: 1. Even in the presence of a postoperative acidity the reduction in free and combined acids is much greater after gastric resection than after gastro-enterostomy. 2. Haberer introduced partial gastrectomy as the operation of choice for duodenal ulcers in 1920. The fact that this operation effects a postoperative anacidity in the majority of the cases was established by Lorenz and Schur¹⁰ in 1922. Haberer planned this operation in order to remove the duodenal ulcer and the ulcer-bearing area (distal half of the stomach). Experience has shown that even in the presence of gastric acidity after partial gastrectomy the incidence of a secondary or recurrent ulcer is much smaller than after gastro-enterostomy or different forms of pyloroplasty.

Paterson¹¹ opened an address on gastric surgery before the British Medical Association in 1926 with the statement that "there is probably no operation in sur-

⁹ Sebening W. Why Partial Gastric Resection is Preferred for Peptic Ulcers in Germany. Proc. Staff Meet. Mayo Clin. 7: 139 (March 9) 1932.

¹⁰ Lorenz H. and Schur H. Unsere Erfahrungen ueber den Wert der Antrumresektion bei der Behandlung des Ulcus pepticum. Arch. f. Klin. Chir. 119: 239 1922.

gery which has added more to the sum of human happiness than gastrojejunostomy." I think that many patients who have had a gastro-enterostomy performed on them will counter with the statement that "there is probably no operation in surgery which has added more to the sum of human unhappiness than gastrojejunostomy," for there are no more agonizing pains than those caused by a gastrojejunal ulcer. After all, the final decision as to the value of any method is always made by the patient. The gospel of gastric resection is spreading among sufferers with ulcer. Many patients have told me that they would not have a gastro-enterostomy performed on them, as they had friends who, far from being improved, had been made much worse by this operation. They prefer the major operation of a partial gastrectomy with a good chance for a complete cure to a gastro-enterostomy with the high incidence of failures. Our follow-up clinic presents an entirely different picture since gastro-enterostomy has been replaced by gastric resection. Complete restoration to health is the rule, complaints about persistent gastric distress are the exception.

AN OUTBREAK OF BOTULISM IN NEW JERSEY

FRANK S. CAPRIO, M.D.

MARION, IND.

Although outbreaks of botulism have previously been reported, little appears about this disease in recent medical literature. An epidemiologic survey of reported cases in the last twenty-two years shows that this disease is far more common in the western United States, particularly along the Pacific coast, and is therefore considered more or less a rarity in the Atlantic coast states. However, it is true that many cases of botulism may have gone unrecognized, probably because of a confusion in diagnosis between this disease and encephalitis, acute poliomyelitis, toxic ophthalmoplegia, and various types of food poisoning.

Because of the extremely high mortality of cases that have occurred in this country, in all probability because botulism had been unsuspected, each individual outbreak merits attention on the basis of presenting new material in the further knowledge and investigation of this disease.

The outbreak described here occurred in Bernardsville, N. J. March 2, 1935, the meal presumably responsible for the onset having been consumed on the preceding day. A family of five, comprising the father, mother, two daughters and the grandfather, became suddenly ill soon after the consumption of a jar of home preserved peppers, served in the course of their meal. The history obtained from the mother relative to the serving of the peppers to all the members of the family together with the nature of the onset and acute symptoms characteristic of a food intoxication, led to the establishment of an early diagnosis of botulism. Two members (the father and the grandfather) died following a relatively short incubation period, before botulinus antitoxin was available. One of the two daughters received antitoxin in addition to all other therapeutic measures but died on the fourth day. The last two members (mother and daughter) were also given botulinus antitoxin in the course of their treatment and fortunately managed to survive, after a stormy convalescence of approximately two weeks.

Although the cases were first seen and diagnosed by the family physician (the author), the patients were placed under the therapeutic and hospital management of Dr. Rodgers of Somerset Hospital, Somerville, N. J., and Drs. S. C. Haven, McClain, C. B. Walker and A. F. Galasso of the Memorial Hospital, Morristown, N. J. Dr. Borow of Bound Brook, N. J., performed the autopsies. The patients were also seen in consultation by Dr. M. J. Rosenau, author of "Preventive Medicine and Hygiene" and member of the Harvard Medical School, Boston, who conducted a personal investigation of this particular outbreak of botulism. He substantiated the original clinical diagnosis and commented on the various phases of the disease.

REPORT OF CASES

CASE 1—Mr. O., aged 51, the father, was the first victim. On March 1, 1935, Mrs. O. opened a jar of home canned peppers and noted a rather peculiar odor but was not certain whether or not the peppers were spoiled. Consequently she proceeded to serve them in the form of a sandwich for her husband's lunch. The victim, noticing nothing peculiar about the taste or odor of his food, consumed his sandwich heartily at noon of the same day. The following morning he started for work but had to return after an hour or so, complaining of a vague pain in the pit of his stomach, dizziness and constipation, in addition to muscular weakness in his arms and legs. These symptoms manifested themselves approximately twenty-one hours after the ingestion of the contaminated food. In the evening of the same day (March 2), when examined for the first time by a physician, the patient complained of dysphagia, nausea and diplopia, with generalized weakness throughout. In view of the suggestive history and the clinical picture, a presumptive diagnosis of botulism was made and the patient was immediately sent to the nearest hospital. On admission his temperature was 97, pulse 70 and respirations 24, and his blood pressure was 110 systolic, 80 diastolic. The abdomen was somewhat distended and tympanic. Mentally he appeared alert, his sensorium was clear, and the pupils were dilated and reacted sluggishly to light and in accommodation. The reflexes were equally hyperactive. The respirations, although normal in rate, were very superficial. He appeared extremely toxic and was unable to express himself clearly. The pulse rate was increased to 112 during the last hour. On admission the patient was given 2 ounces of magnesium sulfate, which he swallowed with difficulty, and 50 cc. of dextrose solution intravenously. A nasal catheter was passed into the stomach, which was washed with a 3 per cent solution of sodium bicarbonate. The patient vomited considerable foul greenish gray contents, resembling spinach in appearance. He was also given constant symptomatic treatment. Botulinus antitoxin was not available at the time. Death occurred at 8:40 a. m. March 3, fifty-two hours and forty minutes after the ingestion of the poisoned food and twenty-three hours after the onset of the disease. The immediate cause of death apparently was respiratory paralysis.

CASE 2—Mr. L., aged 71, the grandfather, who was the next victim complained of dizziness vomiting almost continuously of coffee ground and brown mucoid material with few solid particles, muscular weakness and blurred vision. These symptoms developed approximately thirty-three hours after the ingestion of the responsible food. On admission to the hospital his temperature was 98.6, pulse 74 and respirations 20. Shortly before he died, his temperature was 100.6, pulse 114 and respirations 28. The patient received general treatment, consisting of gastric lavages, catharsis infusions of dextrose, respiratory and cardiac stimulants and oxygen and carbon dioxide inhalations. Specific treatment with botulinus antitoxin was not resorted to as the serum was not available at the time. Death occurred March 3 forty-six hours and twenty minutes after the consumption of the peppers and thirteen hours after the onset of the symptoms. The cause of death also was respiratory failure.

CASE 3—The last victim to die was Miss M. O. aged 23, who complained of extreme muscular weakness, headache, dysphagia and diplopia, twenty-seven hours after the ingestion

of the peppers. On admission to the hospital she appeared acutely ill, weak and toxic. The pupils were equal and reacted to light and in accommodation. There was rather coarse nystagmus on looking to the left. There was an external rectus paralysis on the right side. The breath was offensive. The throat was dry and the patient complained of dysphagia. The temperature was 99.2, pulse and respirations 22. The blood pressure was 125 systolic, 70 diastolic. The day following admission to the hospital she became cyanotic, requiring oxygen and carbon dioxide. Her speech became thickened and she complained of inability to expectorate the mucus that had collected in her throat. As her cyanosis increased she was placed in a respirator and for a time responded favorably. Botulinus antitoxin arrived from the Jensen-Sahsberg Laboratories in Kansas City, Mo., on the second day of hospitalization, at which time 5,000 units of A and B antitoxin was given intravenously, following a negative conjunctival and skin test. She was given 10 per cent dextrose in saline solution intravenously at 11:50 p. m. that day. The patient was able to articulate more distinctly, felt more encouraged, and complained less about mucus collecting in her throat. The following afternoon, March 5, at about 4 p. m., she had a chill and her temperature ascended to 103.4, the pulse was 112, which later became 134, and respirations were 40 per minute. The heart sounds were normal. The patient was given 5,000 more units of A and B serum. Her blood pressure dropped to 98 systolic, 60 diastolic and breathing became shallow. No significant observations were made on percussion or auscultation of the chest. She was given extensive treatment. Just prior to death, however, some coarse rales were elicited over the anterior portion of the chest on both sides. Death occurred apparently from respiratory paralysis. The sudden rise in temperature, in the presence of chills, led to the suspicion of pneumonia setting in as a complication, favored by the patient's apparent exhaustion. This was later confirmed at necropsy. The patient died at 11:32 a. m., March 6 (the fourth day of hospitalization) approximately 120 hours after the ingestion of several slices of peppers.

CASE 4—Mrs. O., aged 46, the mother, did not manifest any symptoms prior to her admission to the hospital. About 1 p. m., March 3, forty-nine hours following the consumption of the contaminated peppers, she complained of diplopia, generalized weakness, and thickening of her speech. She developed a marked ptosis of the upper eyelids with a paresis of both external recti and superior and inferior recti. Five thousand units of A and B botulinus antitoxin was administered intravenously. March 4, the third day, she was unable to swallow liquids and became progressively worse. She received 1,000 cc. of 2.5 per cent dextrose in saline solution. March 5, the fourth day, she was able to speak a little more distinctly. March 6, the fifth day, she was able to take 450 cc. of fluids by mouth. Her vision improved also. March 9, the eighth day, she showed marked improvement. She was able to swallow with a little more success, felt stronger, and could speak and see much better. March 14, thirteen days after onset, she was discharged from the hospital, having obtained maximum benefit from her hospitalization and was allowed to convalesce at home.

CASE 5—Miss B., aged 23, who had practically tasted a slice of pepper, not desiring any more stating that the peppers had a peculiar taste, did not develop symptoms until sixty-nine hours afterward. As a result of having had less of the contaminated food, she had the longest incubation period. She was admitted to the hospital on March 3. The following day she stated that she felt dazed and weak and that things appeared blurred before her eyes. Five thousand units of A and B antitoxin was administered intravenously, following a negative conjunctival and skin test. Eight hours after the serum her temperature ascended from 98.6 to 101, the pulse increased to 120 and respirations became 24. A drooping of the upper eyelids was observed. The pupils reacted to light and in accommodation. March 5, the fourth day, she received an additional 5,000 units of the serum. The day following this last administration of serum she showed a marked improvement. She appeared brighter and subjectively better. She had little difficulty in articulation and in taking fluids, however, the ptosis was still present. She also exhibited some sluggishness of tongue protrusion and lateral deviation. March 12, eleven days after the onset she was placed on a soft diet.

Although weak, she stated that she felt considerably improved. On the thirteenth day she was discharged from the hospital as having sufficiently recovered for convalescence at home.

SYMPTOMATOLOGY AND DIAGNOSIS

The incubation periods varied from twenty-one to sixty-nine hours. The usual incubation period of this disease is from eighteen to thirty-six hours after the ingestion of the toxin, however, symptoms may appear as early as four hours and as late as four days after eating the poisoned food, according to some authorities on the subject. The symptoms manifested in this particular outbreak consisted of: 1. Blurred vision, diplopia, blepharoptosis and photophobia. 2. Lassitude and weakness, particularly in the muscles of the arms and legs. 3. Obstinate constipation. 4. Offensive breath. 5. Dysphagia. The patients also complained of a collection of thick, tenacious mucus in the pharynx, which they attempted to raise with considerable difficulty. 6. Inability to articulate, their tongues seemed thickened and moved slowly, producing unintelligible mumbling whenever speech was attempted. 7. Drowsiness. 8. Normal or subnormal temperature prior to the administration of the serum. 9. Vomiting in one case, followed by frequent eructations of gas. 10. Full possession of mental powers. During the entire course of their illness the patients were consciously aware of the gravity of the situation and dramatically pleading for salvation up to the last minute of respiration.

The diagnostic conclusion that the home canned peppers were responsible for the outbreak was arrived at by a process of elimination. The peppers constituted the only questionable article of food served that had been shared by every member of the family.

The manifestation of the clinical symptoms enumerated led to the establishment of an early diagnosis of botulism at the home of the patients, prior to hospitalization.

Treatment in general consisted of forcing fluids, catharsis, lavage, colonic irrigation, early hospitalization with complete rest in bed (exclusion of visitors), removal of mucus in the pharynx by gentle suction with a soft catheter and by wiping the throat frequently. Sedatives for restlessness and insomnia, special nursing care, cardiac and respiratory stimulants, and maintenance of respiration by means of oxygen and artificial respiration (Drinker respirator).

In addition, botulinus antitoxin A and B combined was administered to three of the patients, two having died before the serum was available. Of the three that received antitoxin, one died from bronchopneumonia, a complication that set in just prior to death, and the two survivors showed a marked improvement in all their symptoms following the use of serum, despite its unavoidably delayed administration.

LABORATORY EXAMINATIONS

Unfortunately, none of the peppers from the suspected jar consumed were obtainable. Specimens of other jars similarly preserved were secured for bacteriologic examination. When injected into guinea-pigs they produced no pathologic effects. No aerobic or anaerobic growth was present in any of these jars. The stomach contents of one of the patients was found to be negative for any of the heavy metals.

Another laboratory reported the following: 1. Toxicologic examination of the stomach contents and of a jar of pickled peppers was found to be negative for volatile mineral, nonvolatile organic and alkaloidal

poisons 2 Cultures of the pickled peppers were found to be negative Cultures of the stomach contents produced luxuriant, anaerobic growths but no *Bacillus botulinus* and had no effect on guinea-pigs, when injected

The third laboratory (state department of health) also reported negative results for *Bacillus botulinus* and for the toxin of these bacilli

In only a few cases out of many outbreaks of botulism has the laboratory been able to demonstrate positive evidence substantiating the clinical diagnosis

NECROPSY

The following is a necropsy report of the first victim

The body was that of a small, well developed stocky white man, bald headed, with gray hair There was an incision, well healed in the right upper quadrant, about 5 inches in length Rigor mortis had set in

The skull cavity showed no hemorrhage There was some oozing of the cerebrospinal fluid, which was clear when the brain was removed There was slight edema and softness of the brain tissue

There was no free fluid in the thoracic cavity The lungs were markedly congested, showing chronic passive congestion No consolidation or hemorrhage was noted

The heart was dark and seemed normal, outside of a chronic passive congestion

The abdominal cavity had marked adhesions to the abdominal sear, especially in the omentum The stomach was fairly well dilated and full of foul greenish gray contents which had a peculiar foul odor Part of the contents were saved for chemical examination The stomach had a gastro ileostomy look-up of the posterior type, one portion of the stomach being about 9 inches from the cecum, so that obviously food must have passed from the stomach into the large intestine very rapidly

The appendix was missing When the stomach was opened the mucosa showed marked hemorrhages throughout although there were no ulcerations the hemorrhages were worse at the cardiac end of the stomach The small intestine was full of thick mucus and was congested The liver was small, turgid in color showed marked chronic passive congestion, and was soft The spleen was very soft, was of about average size and the pulp scraped off readily It seemed to act like jello The kidneys were turgid and congested the cortex was of about average size and the capsule stripped readily The bladder was not remarkable The pancreas was very soft and hemorrhagic

Gross Pathologic Examination—The heart showed moderate atheromatous changes in the mitral and aortic valves

The lungs showed intense congestion

The stomach contained submucosal hemorrhages in the region of the fundus

The kidneys contained an excessive amount of pelvic fat The parenchyma was congested but the markings were distinct

The spleen was fairly dry and fibrous

The liver showed no gross changes

The small intestine showed an excessive amount of mucus covering the mucosa

The brain showed mild pial congestion but otherwise the surface appeared normal Sections of the cerebral hemispheres midbrain pons dura and cerebellum showed no gross abnormality Microscopic sections were taken of the cortex and the anterior quadrigeminal body

Microscopic Pathologic Examination—The stomach showed no pathologic changes

The liver showed moderate infiltration of the central cells with pigment there was chronic passive congestion

No changes were noted in the heart

Peculiar pigmentary deposits were scattered throughout the kidneys Some cloudy swelling of the tubules was present

The lungs showed marked congestion and edema

Sections of the brain showed the blood vessels to be clear There was no inflammatory reaction There was a slight increase in the oligodendroglia and the neuron cells showed mild disorganization of the tigroid substance and the nuclei were occasionally eccentric

Summary—1 Acute toxic poisoning 2 Chronic passive congestion of all organs 3 Hemorrhage into the stomach
Impression Toxic neuronophagia
The poison seemed to come from the toxin of the bacillus of botulism

SUMMARY

1 A diagnosis of botulism was made on the presentation of a history of having consumed a jar of home canned peppers (having a peculiar taste), and on the basis of the clinical symptoms characteristic of the disease

2 The clinical diagnosis of botulism was substantiated by the necropsy report

3 The symptoms of the disease manifested themselves in proportion to the quantity of toxin ingested One of the survivors, who had the least amount of the contaminated peppers, had the longest incubation period

4 The symptoms were those of a profound systemic toxemia, characterized by oculomotor disturbance, drowsiness, weakness, and disturbance in the secretions of the throat

5 An early recognition and diagnosis of botulism intoxication is extremely important When the diagnosis is established, botulinus antitoxin should be administered as early as possible Five thousand units of type A and B, to be repeated as often as is necessary, should be given intravenously Despite the delayed administration of serum in this particular outbreak, there appeared a marked change of improvement in all the symptoms of the two survivors

6 Death apparently occurred from respiratory paralysis due to the action of the toxin in the cells of the central nervous system

7 Botulism should be differentiated from food poisoning The latter has a shorter incubation period and, while the symptoms are alarming, the mortality is low In botulism the symptoms are severe and the mortality is high

8 The necropsy report revealed a toxic neuronophagia and a chronic passive congestion of all organs

9 Botulism is far more common in the Pacific Coast states This outbreak is one of a few that have occurred in the East

10 There are only two other cases on record in medical literature of botulism caused from home canned peppers These cases occurred in California and proved fatal

11 Although convalescence is extremely slow, the two survivors manifested no permanent disability from this disease and have fully regained their former condition of health

COMMENT

1 The control of similar outbreaks of botulism can be brought about only through an accurate recognition of the symptoms and an immediate report of cases

2 Measures should be taken to have botulinus antitoxin immediately available when needed, as a means of offering each patient the maximum hope of recovery

3 Prevention of botulism should consist in a widespread campaign of education relative to proper methods of the home canning of vegetables and fruits

4 The extremely high mortality of botulism is a challenge to medical science and deserves continued investigation and research Perhaps consolation for the slow rate of progress in the scientific knowledge of this disease may be found in the words of the poet "Whither we cannot fly, we must go limping"

WALTER C POPP, MD

ROCHESTER, MINN

It has become a sort of fashion, among those who write about the therapeutic value of heat, to trace it back to the Romans and the Greeks. What a tremendous burden of responsibility has been thrown on the Romans and the Greeks for so many things sacred or profane! During the height of the Roman Empire there were, in Rome proper, a large number of public bathing establishments, some of which were enormous and imposing institutions, such as the baths of Caracalla and those of Diocletian. The baths of Caracalla, for instance, occupied a building almost 1,200 feet square. In this mammoth structure were a series of pools, in each of which the water was kept at a different temperature from hot to cool, in each pool the temperature of the water was maintained by special heating arrangements. Besides these pools there were rooms for epilation, for massage and for various other procedures. It was the fashion at that time, among the young bloods and gay sophisticates of Rome, to go to these bathing establishments for a hot bath and rub, followed by epilation and by anointment with various aromatic and cosmetic preparations, after which they went forth resplendent and smelling as one does when one leaves certain barber shops. Practices such as these can hardly be looked on as therapeutic procedures, they smack altogether too much of ordinary hygiene and cosmetic efforts, with emphasis on the latter. In any event, the use of heat under these circumstances was entirely empirical and can hardly be dignified by the name of heat therapy.

The empirical use of heat for relief of various human ailments is as old as the human race. More than 4,000 years ago the Chinese used heat extensively and with about as much knowledge as the Romans. The only difference between the two was that the Romans made such practices fashionable and popular and provided for them in numerous, elaborate and imposing edifices.

In Japan, since about 1700, the famous natural springs of Kusatsu have been used for the empirical treatment of syphilis, arthritis, gout and many other disorders. The water in these springs issues from volcanic formations at temperatures varying from 37.7 to 71.1 C (100 to 160 F). For convenience, small individual tanks are placed in the pools and, if the water happens to be too hot for a particular bather, he stirs it with a large wooden paddle until he thinks it is cool enough to bear. Then he immerses himself up to the neck and remains in this hot water as long as possible, usually this is a matter of from three to six minutes, when he emerges looking almost like a boiled lobster. Such immersions are repeated several times a day and are continued for from three to five weeks. Distinctly beneficial results are often observed. But again the procedures surrounding the use of heat under these conditions are clearly empirical.

True fever therapy, as it is now understood, originated with Wagner-Jauregg, who made it known in

1918. It was he who found that inoculation with malaria of a patient suffering from dementia paralytica is often followed by improvement or complete remission of symptoms. Since then, malarial therapy has had a considerable vogue. In the hands of some the results have been excellent, in the hands of others the results have not been so good. This variation in results has probably been due to a number of factors, one of which undoubtedly has been the facility with which malarial therapy could be used under satisfactory conditions.

Since then, many other methods of inducing fever artificially have been employed. Among these may be mentioned injections of crystalloid or colloid substances, or of heteroproteins such as peptone, milk and casein. Others have injected vaccines prepared from paratyphoid micro-organisms or from *Haemophilus Ducreyi* (dmelcos). These different methods, which are sometimes classified under the designation physiologic but which should perhaps more truthfully be classified under the designation pathologic, have been used with varying degrees of success. A number of objections have been raised against them. The most important objections have been the uncertainty of the resulting fever and the difficulty of regulating the fever. For these reasons, many physicians have continued to seek more satisfactory methods of raising the temperature of patients for therapeutic purposes.

Among the various physical methods that have been tried may be mentioned hot baths, diathermy, short-wave diathermy, radiant light (infra-red generator or carbon filament lamps), inductotherapy, and air-conditioned chambers. Hot baths can be used effectively when the period of fever need not be long, but when it is desirable to maintain the fever for an extended period (several hours) this method becomes a distressing and debilitating experience for the patient and is difficult to use satisfactorily. Diathermy has been found effective. This method requires the application to the patient of large ventral and dorsal electrodes, which must be carefully maintained in contact with the skin over a large area. This involves the use of a large jacket, which is firmly laced around the patient in order to maintain the required contact between the electrodes and the skin. Even with such a jacket, however, contact may be broken by movements of the patient, and burns may result. Moreover, the method makes it impossible to keep the skin beneath the electrodes under observation. Another objection is that the fairly tight lacing of the jacket gives the patient a sense of constriction and respiratory oppression that is decidedly uncomfortable. Short-wave diathermy has been used with considerable success, especially in Europe, although its therapeutic possibilities were first recognized in this country. Until simpler and more effective means became available, simple diathermy and short-wave diathermy were the best methods of inducing fever. The use of short-wave apparatus, however, cannot be described as a simple procedure. The apparatus itself is somewhat complicated and its operation is fraught with various technical difficulties,¹ such as the tendency of the current to arc to pools of perspiration and the constant necessity of causing the perspiration to evaporate from the skin as rapidly as it is formed. This requires more or less elaborate accessory equipment.

From the Section on Therapeutic Radiology (Dr. Desjardins and Dr. Popp) and the Section on Urology (Dr. Stuhler) the Mayo Clinic.

1 This does not apply to the use of short wave apparatus for local heating only. Also in apparatus of this type manufactured in Europe some of these difficulties have been partly eliminated.

Radiant light fever chambers are being used with more or less satisfaction. One point in their favor is that they are less expensive than certain other types of apparatus designed for this purpose. A disadvantage, however, is that, with most chambers of this type, the elevation of temperature is rather slow. In treating certain conditions which require that a high temperature be maintained for several hours, undue slowness in inducing fever becomes an important objection, because the patient becomes fatigued before his temperature has risen to the level at which it is to be maintained.

Of the different types of physical apparatus thus far designed for fever therapy, the one which appeals to us as the most effective from all points of view is the air-conditioned chamber known as the Kettering hypertherm. With this chamber the temperature can be raised more rapidly than with radiant light chambers and any degree of fever can be attained and maintained for as long as the condition of the patient allows or requires. Moreover, the patient's body (except the head, which is outside) is entirely free within the chamber, and the apparatus does not involve the use of contact electrodes, condenser plates or other electric gadgets of any kind.

AIR-CONDITIONED FEVER CHAMBER (KETTERING HYPERTHERM²)

This chamber (fig 1) consists of a rectangular box about 6 feet long, 30 inches high and 36 inches wide, mounted horizontally on long legs and divided into two unequal parts: one, the main compartment occupied by the patient, is large enough to accommodate the trunk and extremities, the other is a small, shallow compartment at the foot of the chamber and separated from the main compartment by an asbestos partition, in which is a small, open grill, in this smaller compartment is mounted the simple mechanism designed to heat and humidify the air as well as to force it to circulate through the chamber proper. The ceiling of the chamber is double, and the anterior third of the inner layer of the ceiling contains a large number of holes, through which the heated and humidified air furnished by the generating mechanism penetrates the main compartment of the chamber and circulates around the patient. The floor of the chamber also is double, and its inner layer constitutes a bed which, moving smoothly on brass rollers, can be rolled into the chamber or withdrawn from it with little effort. The bed is covered with a comfortable air mattress. The two legs supporting the head end of the chamber are double, and one set, forming an integral part of the rolling bed, is fitted with casters to facilitate the inward or outward movement of the bed.

At the head end of this bed is a projecting shelf, which remains outside the chamber when it is closed and on which rests the head of the patient. This end of the chamber can be closed by means of a vertical panel which, sliding in metal grooves at each side, can readily be lowered or raised. Once closed, this panel is firmly held in place by two large hand screws. One turn of these screws permits the panel to be quickly raised, and the patient can thus be withdrawn from the chamber in five seconds. In the center of the lower border of the vertical panel is a rather large and deep, circular indentation that surrounds the patient's neck. Within this main indentation is fixed a piece of sponge rubber, in which a smaller, secondary indentation fits loosely around the neck. In order to provide for variations in the size of the neck of different patients, and to prevent the escape of air, which would reduce the efficiency of the apparatus and interfere with treatment, the space between the rubber and the neck is loosely packed with a towel.

The side walls and ceiling of the chamber are made of heavy celotex, while the floor is made of wood. It is essential that the chamber should be as air tight as possible.

The thermogenic mechanism consists of a small electric air heater, with three units, this is controlled by external switches which make it possible to use one or all three units at will, and also by a thermostat which permits one to regulate the temperature of the air within the chamber, and a pan of water heated by two small electric elements, the heating of the water for humidification being regulated by an automatic humidistat. But, in order to avoid uncertainty about the degree of humidity, this factor is verified by dry and wet thermometric readings. The data thus obtained permit the exact calculation of the degree of humidity. The heated and humidified air thus produced is then forced by an electric blower between the two layers of the ceiling of the chamber, whence it enters the main compartment through the holes in the anterior portion of the inner layer of the ceiling, circulates around the patient about ten times a minute, and returns to the heating and humidifying mechanism through the grill in the partition that separates the patient from the mechanism.

By means of panels sliding in metal grooves at each side, it is possible to keep the patient's skin under observation, to take the blood pressure as often as may be necessary, and to take the rectal temperature every few minutes. Moreover, in case of emergency the patient may be withdrawn from the chamber in a few seconds. These undoubtedly are advantages which are not provided for to the same degree by any other method or apparatus with which we are acquainted.

Later, it is possible that more simple and less costly apparatus may be conceived and constructed. For example, chambers with infra-red elements or carbon filament lamps, or apparatus incorporating the principle of inductothermy, may be perfected so as to do away with the present disadvantages. But however simple the thermogenic methods may become, it is doubtful whether fever therapy, especially for diseases of which the treatment requires that a high temperature be maintained for hours, will ever be an office procedure.

An essential point is that, throughout a session of treatment, the patients must be under the constant observation of specially selected and trained nurse-technicians and that the technical personnel should be constantly supervised by a physician familiar with all

² This apparatus was conceived and perfected at the Miami Valley Hospital and at the Research Laboratories of the Frigidaire Division of the General Motors Corporation, Dayton, Ohio, by Dr. Walter M. Simpson with the collaboration of Mr. Charles F. Kettering, director of the Research Laboratories of the General Motors Corporation, and Mr. Edwin C. Sittler of the Research Laboratories of the Frigidaire Division of the General Motors Corporation. The apparatus is not on the market and because of the danger of unscrupulous exploitation, probably never will be as far as outright sale is concerned. At present a smaller, simpler and less costly apparatus is being developed. If later its wider distribution should seem desirable, the apparatus will probably be ceded on a loan-lease basis to selected institutions. Fifty-five of the units have been lent to twenty medical research centers, strictly for investigative purposes. The production and maintenance of artificial fever therapy at high temperature is not adaptable to ordinary office practice. The physician and nurses charged with this undertaking received special training in the Department of Fever Therapy Research at the Miami Valley Hospital before the apparatus was released. Adequate preliminary training of physician personnel and nurse personnel is an essential requirement for this type of work. We are indebted to Dr. Simpson and Mr. Kettering for the privilege of using this apparatus. Four hypertherms being now in constant operation at the Mayo Clinic.

phases of the method. The technicians are not allowed to leave the patient until the session of fever has been completed and until the temperature has returned to normal. If a technician must absent herself momentarily, her place is taken by another technician or by the supervising physician. Lunch for doctor and nurses is served in one of the treatment rooms or in the office. Under such conditions, and if the patients are carefully selected, only minor complications are likely to occur. Slight circulatory incidents (pulse), gastro-intestinal disturbances (nausea and vomiting), or muscular tetany (hands, feet or abdominal wall), may occur in a few cases, but, rapidly arrested by appropriate measures, they do not interfere with treatment.

GENERAL CONSIDERATIONS

Those who attended the twenty-third French Congress of Medicine, held at Quebec in August 1934,

specially trained team remove practically all danger of serious complications and make possible the cure of a high percentage of acute or chronic gonococcal infections of the urethra, epididymis, cervix and body of the uterus, fallopian tubes and joints, and this within a period which may vary between two and four weeks but which, in the majority of cases, varies between two and three weeks.

When the treatment was given with the thermogenic means available at the time (simple diathermy or short-wave diathermy), we agree with Halphen and Auclair that the procedure was really tedious and exhausting, and that the results were uncertain and far from striking. But that period of trial is over. Now it is possible to cure most patients who have simple gonorrhea or gonorrhea complicated by epididymitis, metritis, salpingitis or arthritis, whether the infection is acute or chronic. And the certainty of cure is such that, if

heard the interesting reports of Richet, Roger, Fribourg-Blanc, Halphen and Auclair, and Bessemans, on the biologic agents suitable for inducing fever therapy for certain diseases of the nervous system, for infections and diseases of nutrition and of the blood, for syphilis, and on physical methods of thermogenesis. In their report, Halphen and Auclair mentioned fever therapy for acute gonorrhea and gonococcal arthritis in the following terms: "It is a tedious and dangerous procedure, hardly in keeping with the relative benignity of the disease or with the results obtained, at least in man." At the time this judgment was pronounced it was approximately accurate but at the present it is no longer valid. Although fever therapy at high temperature may be somewhat tedious, the improvement of physical thermogenic apparatus, the judicious selection of patients, and a painstaking technic carried out by a

patient returns three or more weeks later and tries to make us believe that a fresh discharge is evidence of recurring infection, we know that this is not true and we always succeed in making the patient admit a recent sexual indiscretion.

If a few cases of gonococcal infection prove rebellious to treatment, this is because certain strains of gonococcus can tolerate a temperature of from 41.1 to 41.7 C (106 to 107 F) for a longer time than can certain patients. Fortunately, the number of such cases is small. Another reservation must be made. In certain women suffering from gonorrhea complicated by infection of Skene's glands, that part of the infection which involves the urethra, uterus, tubes or articulations rapidly disappears under the bactericidal and resolving influence of a sufficiently high temperature maintained for from six to ten hours and repeated three or more

times at intervals of two days. But to cure the infection of Skene's glands it is sometimes necessary to cauterize these structures.

GNOCOCCIC INFECTION

Bactericidal Action of Heat on the Gonococcus—Antecedent reports of cases are often interesting and sometimes throw light on certain questions. Thus, Bogdan³ recorded a case of gonorrhea in which the urethral discharge ceased during a pneumonia but reappeared after the fever had subsided. Finger, Ghon and Schlagenhauser⁴ found it impossible to induce urethritis by injecting gonococci into the urethra of a patient whose temperature varied between 39 and 40 C, while urethritis always supervened after similar injections into patients without fever. Guiard⁵ reported a case of gonorrhea in which the urethral infection disappeared spontaneously during an attack of scarlet fever. Neisser and Scholtz⁶ testified to a constant difficulty in cultivating the gonococcus from febrile patients. Luys⁷ made a similar observation in a case in which the temperature, during an attack of mumps, rose to 40 C. Culver⁸ had the same experience, a urethral infection disappeared in the course of an attack of malaria lasting four days, in the course of which the patient's temperature rose to 40.5 C. Culver claimed that a sudden rise of temperature to 39 C suffices to destroy the gonococcus. However, the observations of Nobl⁹ and of Nicoll¹⁰ do not seem to corroborate Culver's assertion.

Bacteriologists have long known that the gonococcus can best be isolated and cultured at a temperature of 37 C and that the organism does not grow so well at a temperature higher than 38 C. Steinschneider and Schaffer¹¹ noted that a temperature between 40 and 41 C, maintained for a few hours, is sufficient to destroy the gonococcus. Wertheim¹² claimed that the organism grows well at 40 C and may even tolerate a temperature of 42 C, but his results were not confirmed by those of other investigators. Santos¹³ succeeded in isolating the gonococcus from pus that had been subjected to a temperature of 45 C for forty-five minutes. By heating the male urethra by means of diathermy, on the other hand, Boerner and Santos¹⁴ could not isolate the organism

after ten hours of temperature at 39 C, three hours at 41 C, and fifty-seven minutes at 41.7 C. Ylppo¹⁵ treated a vulvovaginitis of a girl, aged 5 years, by means of hot baths, beginning with a temperature of 39 C and increasing the temperature of the water to 41.5 C. After eight daily baths, each lasting one hour, Ylppo could no longer isolate the gonococcus. Ungermann¹⁶ found that certain strains of gonococcus can withstand a temperature of 41 C for ten hours and that a few strains may even tolerate a temperature of 52 C for seven hours.

Koch and Cohn¹⁷ were of the opinion that the gonococcus can tolerate a high temperature in vivo more readily than in vitro. This opinion was based on the fact that, in the course of an acute infection in man, gonococcal infection can resist a temperature of 40 C for several days. These different observations and results give an impression of divergence but, when they are analyzed in relation to the degree of temperature and to the duration of temperature, the impression of divergence diminishes. The remaining portion, which

Fig 2—The open chamber with a patient ready to begin a session of treatment (side panel open)

cannot be accounted for by these two factors, is probably due to the variable tolerance to temperature of different strains of gonococcus.

In spite of the apparent significance of the preceding observations, fever therapy for simple or complicated gonococcal urethritis owes still more to the investigations of Carpenter, Boak, Mucci and Warren,¹⁸ who undertook a systematic determination of the influence of heat on the gonococcus. Their specific aim was to determine the degree and duration of temperature that can be tolerated by man and are necessary to destroy this microbe. With this object in view, they subjected fifteen strains of gonococcus to temperatures of 39, 40, 41, 41.5 and 42 C. All the strains of gonococcus that they studied had been cultivated from one month

to twelve years. The ability of the different strains to withstand the temperatures mentioned varied considerably. The cultures isolated ten or twelve years previously tolerated heat for a longer time than the recent cultures. In spite of this variation in tolerance, 99 per cent of the gonococci could not withstand a temperature of 41 C more than four or five hours, but 1 per cent was not destroyed until this temperature had been maintained for twenty-three hours. When subjected to a temperature of from 41.5 to 42 C, 99 per cent of the gonococci were destroyed in two hours, but 1 per cent had to be heated at 41.5 C for from seven to twenty hours, or at 42 C for from five to fifteen hours, to effect their destruction. It is to these thorough investigations of Carpenter, Boak, Mucci and Warren that we owe the possibility of rapidly curing gonococcal infection. At present the gonococcus is the only micro-organism of which the lethal temperature has been determined and which can be tolerated by human beings. It is possible that the future may furnish equally favorable data on other bacteria, in this event the field of therapeutic hyperpyrexia will be correspondingly extended. By this it is not intended to imply

Fig. 3—The chamber closed and a session of treatment started. The fan blows cool air around the patient's head and the technician passes over the patient's face towels dipped in ice water.

that fever therapy has no other basis than a knowledge of the temperature necessary to destroy other bacteria effectively and cure other diseases. Far from it. But in those other diseases one must depend on the indirect effects of heat, while in gonococcal infection the cure is mainly, if not wholly, a question of degree of temperature and duration of temperature, consequently, the principal, and perhaps the entire, effect is direct and specific.

CONTRAINDICATIONS

Advanced age with its cardiovascular changes, and organic lesions of the heart at any age, are outstanding and more or less formidable handicaps to fever therapy. Functional disorders of the heart may or may not interfere with treatment. Severe renal disturbances also may make effective fever therapy difficult or impossible but, on the whole, they interfere with treatment less than cardiac or cardiovascular disturbances. Pulmonary tuberculosis per se is not a contraindication, but the resulting impairment of respiratory function may make it impossible to raise the patient's temperature to the required level or to maintain it at this level for a sufficient period. When diabetes is under satisfactory clinical control, fever therapy is not contraindicated.

TECHNIC

The patients are first submitted to a general examination in order to eliminate those whose cardiovascular or renal condition might contraindicate fever therapy. In those cases in which the clinician may be slightly uncertain, electrocardiography and a functional examination of the vessels serve to clarify the situation. If the condition of a patient still remains in doubt, he is subjected to a trial session of fever therapy and, if this is well tolerated, the treatment is continued until the disease is arrested. As a matter of fact, the number of cases with definite contraindications is small. In general, the age of gonorrhea is the age of physical vigor. It may occasionally happen that a person 60 or more years of age may succumb to temptation, and this indiscretion may have a rather introspective sequel, so to speak, but such cases are exceptional.

After having been weighed, the patients, completely undressed but temporarily covered with a bath robe, enter the chamber at about 8 o'clock in the morning, without breakfast. The chamber is already warm, the mechanism having been run for about half an hour. The feet and legs are covered with boots of cotton and gauze to prevent the concentration of heat at the toes and around the bony prominences of the ankles (fig 2). The blood pressure is taken and the chamber is closed. The indentation in the piece of sponge rubber fixed to the lower border of the vertical panel is adjusted around the patient's neck and, in order to prevent excessive leakage of air, a towel is loosely stuffed into the space between the neck and the sponge rubber. The bath robe is then removed from the patient and the session begins.

The temperature of some patients rises to 41.1 C (106 F) in sixty minutes, in other cases such a rise in temperature may require from seventy-five to ninety minutes. At the outset and as long as the rectal temperature does not exceed 40 C (104 F) the temperature is taken every fifteen minutes, but beyond 40 C (104 F) the rectal temperature is taken every five or ten minutes.

Certain authors have advocated the use of a recording electric thermometer, with a thermocouple in the rectum. We have tried instruments of this kind, but they have an appreciable and disconcerting lag. Every mechanical instrument is subject to breakdown, which may be all the more serious because the personnel naturally tends to rely on its automatic operation. Moreover, when a nurse is given a dial or scale to watch and is instructed to govern her actions by its indications, her attention is focused on the dial or scale rather than on the patient. Our experience with recording thermometers has led us to prefer an ordinary thermometer, because of its greater reliability but also because the manual method of taking the temperature gives the technician an additional opportunity to watch the patient.

At the beginning of each session of treatment, when the temperature passes from 39 to 40 C (102.2 to 104 F), one often observes a period of mild excitement, which has been called the "hurdle" and which probably is a defensive reaction of the body to the accumulation of heat. Once this physiologic hurdle has been passed, the patient becomes more quiet and may go to sleep, while the temperature rises rapidly. If the patient is nervous, pentobarbital sodium or codeine is adminis-

tered to help him over the "hurdle." In order to make the sessions less tedious and uncomfortable, a well protected electric fan blows fresh air around the head of the patient, and throughout the sessions the technician passes over the patient's face and head towels dipped in ice water (fig 3). True delirium rarely occurs. When the temperature is between 41.1 and 41.7 C (106 and 107 F), certain nervous patients show a certain degree of excitement. Usually codeine or sodium amytal suffices to quiet them. Just as important and

Fig 4—Chart of temperature and pulse throughout a ten hour session of fever between 106.5 and 107.2 F.

effective is the influence of the technician who knowing her patient, reads, tells stories or allows him to sleep, according to the psychologic indications. This is one of the reasons why the technicians should be carefully chosen, they must be able to adapt themselves to the temperament of their patients, some of whom may be simple and phlegmatic farmers, while others may be cultured, sophisticated or neurotic individuals. Morphine is used as little as possible, because of its well known tendency to induce nausea and vomiting. However, in certain patients who without it, would be difficult to control, a limited use of the drug is made.

Skill in fever therapy is shown by the ability of the technician to maintain the temperature of a patient within one degree at any level, but, in the case of gonococcal infections, between 41.1 and 41.7 C (106 and 107 F), such skill requires intelligence, thorough training and experience. A superior technician can often keep the temperature between 41.4 and 41.7 C (106.5 and 107 F) for ten or more consecutive hours (fig 4).

An observation that is interesting but without significance may be mentioned. Between 11:30 a.m. and 1 p.m. many patients exhibit a mild degree of agitation. This is probably due to the habit of the stomach of being fed at this hour. When this phase of agitation appears, a sedative is given and quiet is soon restored.

As the temperature rises the patient perspires more and more freely and if appropriate measures were not taken loss of weight (from 1 to 5 pounds, from loss of water) and pronounced weakness for several days (from loss of chlorides) would result. To prevent these complications, the patient is made to drink throughout each session of treatment from 2 to 5 liters of 0.6 per cent saline solution (iced). After the temperature has risen above 40 C the majority of patients no longer taste the salt and do not object to it; on the contrary, they continually ask for more. In some cases in which the taste of salt persists and is unpleasant to the patient salt water is alternated with fresh water. With this regimen the weight of most patients, instead of falling, increases from 1 to 5 pounds, and the ensuing weakness is not only less pronounced but lasts only twelve

to twenty-four hours (fig 5). Of 100 patients weighed before and after treatment, the weight of seventy-nine had increased by from 1 to 5 pounds, the weight of twenty patients had diminished because, for various reasons, they had not taken a sufficient quantity of saline solution. Many of these patients had been treated in the early phase before we had learned to prevent or to control nausea and vomiting.

During each session of treatment the condition of the skin frequently is observed and if an area of erythema appears, it is first covered with a towel in order to prevent the direct impact of hot air. If, as sometimes happens this is not sufficient, the erythematous area is covered with a piece of ice for fifteen or thirty minutes, and the erythema usually subsides. These measures make it possible to avoid burns. In a few cases however, small vesicular burns may result from a local deficiency of the sudoriferous glands or blood vessels, but frequent and careful examination of the skin enables one to prevent them or to make them insignificant. If the temperature of a patient is allowed to rise too rapidly, the skin may not have time to adapt itself and may show signs of overheating. Also, the skin of some patients is more sensitive than that of others. On this account, at the first session or two, it may be difficult to raise the temperature to the required level. When the difficulty arises from a tendency to diffuse erythema from an extensive functional inefficiency of the sudoriferous system, the problem may solve itself. One or two sessions of moderate fever may so increase the functional capacity of the perspiratory mechanism that more effective treatment may subsequently become feasible. In a few cases in which the skin is exceptionally sensitive, it is sometimes

Fig 5—Chart showing that the weight of the majority of patients increases during a session of treatment and that there is no connection between weight and number of leukocytes per cubic centimeter of blood.

necessary to bandage the extremities. Because of the tendency of heat to concentrate on small parts, the skin of the extremities usually is more sensitive than that of the trunk. The skin of the female also is more sensitive than that of the male, although this rule is not absolute; exceptions are not rare.

The rate at which the temperature rises is related to the sensitiveness of the skin, the cutaneous distribution and function of the sudoriferous glands, and the

functional activity of the heart and lungs. In two cases we have observed that, even at a temperature of 39.3 C (102.7 F), there was no evidence of perspiration, the skin was excessively red and dry, and the patients complained bitterly. In such unusual cases it is important not to force matters, under penalty of a serious accident. It is wise to proceed more slowly. At the first session, as soon as the functional deficiency of the skin becomes apparent, too rapid a rise in temperature is to be avoided so as to permit the skin to adapt itself to the new conditions. If, nevertheless, the skin shows itself unable efficiently to dissipate the heat brought to the surface by the blood, the patient's temperature should not be allowed to rise above 39 or 39.5 C (102.2 or 103.1 F). Such conduct during the first session or two of treatment is usually rewarded by functional improvement of the skin and subsequent sessions may proceed normally. The temperature of the same patients may then be carried to 41.1 C or even to 41.7 C without further difficulty.

At the first session of treatment, regardless of the behavior of the skin, it is unwise to allow the temperature to rise above 106.5 F (41.4 C) at any time. Not only the skin but the heart, lungs and blood vessels should be given an opportunity to adapt themselves to the treatment; these structures should not be exposed suddenly to the undue functional stress of a temperature higher than that mentioned. In other words, the first session should always be regarded as a test session, and the ability of the patient's cardiovascular, respiratory and cutaneous systems to tolerate a high temperature should be closely observed. If this is not done, serious complications may occasionally arise.

Food is not permitted during the sessions of treatment but, as soon as a session has been completed and the patient's temperature has returned to normal, the patient is given as much milk as he will drink and is urged to take more milk at frequent intervals during the ensuing twenty-four hours. Sometimes a patient may violate the rule of going without breakfast, but the nausea and vomiting which usually follow soon convince him that the rule was not made without a good reason. Sometimes, especially in female patients, nausea and vomiting may occur in spite of abstinence from food on the morning of a session of treatment. This difficulty is rapidly corrected by injecting into a vein from 500 to 1,000 cc of a solution containing 10 per cent of dextrose and 1 per cent of sodium chloride, and the session need not be interrupted. If this difficulty were not so readily corrected, the patient would be unable to take a sufficient quantity of saline solution and the treatment would probably have to be interrupted. In the majority of cases, however, nausea and vomiting occur after the session of treatment has ended and probably result from overfilling the stomach with saline solution at some stage of treatment. Spontaneous evacuation of the mass of liquid usually terminates the disturbance.

How Do Patients Tolerate a High Temperature for Several Hours?—The majority of patients tolerate the treatment quite well, and their behavior is a faithful reflection of the character and temperament of the individual. The poised person, who is determined to get well as rapidly as possible, behaves accordingly. Some patients hum, sing, smoke, or amuse themselves by teasing the technician. Some remain quiet and sleep much of the time. Others, with less will power or whose

nervous system is less stable, complain more or less. Certain nervous individuals, persons without will power or fortitude, or those who have never known the meaning of self control, beg to be released from the chamber long before the session is scheduled to end. But, after one or two sessions, most patients become accustomed and their apprehension diminishes more or less. Naturally, the necessity of spending from six to ten hours at a temperature of 41.1 or 41.7 C (106 or 107 F) can hardly be described as a vacation sport, but there is a clear difference between a natural fever, such as that which arises from a spontaneous infection, and the hyperpyrexia produced by a physical method. The first may be accompanied by chills, while the last does not have any toxic factor and is free from chills. This is an essential distinction. All the physicians and nurses in the service have had a session of fever for personal experience and, before any patients are treated in a newly installed chamber, its operation is tested by ourselves. The experience of a session of treatment is not at all terrifying.

How Many Sessions of Treatment Are Necessary to Cure a Gonococcal Infection?—In the majority of cases, that is in 90 per cent, from three to six sessions are required to cure the disease, and the cure is complete and permanent. In many cases smears of urethral pus do not reveal any gonococci, or attempts to culture the gonococcus are unsuccessful, after the first or second session of treatment but, in order to prevent all danger of recurrence, the patient is given two additional sessions. In some cases the smears and cultures do not become negative until after the third, fourth, fifth or even the sixth session, and in a few exceptional cases, in which the gonococcus is unusually resistant, a cure is obtained only after eight, ten or twelve sessions. In all cases, smears and cultures are prepared the second day after the second session of treatment. Until recently, the gonococcus could be cultured only with difficulty and considerable uncertainty, for this reason, smears were more reliable. But the method of culture recently devised by McLeod, Coates, Happold, Priestley and Wheatley,¹⁹ especially as simplified by Thompson,²⁰ has so well overcome the former obstacles that culture now is a more delicate and reliable diagnostic method than smears.

Duration of Sessions of Treatment—The duration of the sessions of hyperpyrexia varies according to the relative resistance of the gonococcus in each case. As we have already pointed out, the destruction of the micro-organism depends on two main factors: degree of temperature and duration of temperature. The relative importance of these two factors is approximately equal. If a sufficiently high degree of temperature (from 41.1 to 41.7 C, or 106 to 107 F) is not attained, if this degree of temperature is not maintained long enough (from six to ten hours), if the number of sessions is not sufficient, or if the interval between sessions is too long, the infection is not completely or permanently cured. Were it feasible to give the entire treatment in a single session, even if such a session had to be prolonged to ten, twelve or even twenty consecutive

hours, the results would be equally good. Carpenter and Warren, at Rochester, N. Y., have adopted this mode of procedure, but in the majority of clinics and hospitals such a technic would be difficult or impossible.

At the beginning, in our service, the sessions of fever lasted five hours and were repeated only when the urethral or vaginal discharge reappeared, that is, after from three to seven days. It soon became evident that in many cases the sessions were too short and the interval between sessions too long. Since then the technic has been modified. At present the first two sessions are regarded as test sessions and last six hours, by which is meant six hours of temperature between 41.1 and 41.7 C (106 and 107 F). Since the phase of elevation of temperature varies between sixty and ninety minutes, and since the phase of return to normal at the end of each session is approximately as long, the total duration of the session varies from eight to nine hours. An interval of two days separates the two initial sessions as well as all other sessions. If, after the second session, the urethral or vaginal discharge has ceased, and if the smears and cultures no longer show gonococci, two sessions of the same length and at the same interval complete the treatment. But if, after the second session, the discharge continues, or if smears or cultures still disclose gonococci, the duration of the sessions is increased to eight hours (total duration, ten or eleven hours). Then, if one session of eight hours does not suffice to destroy all the gonococci, the subsequent session is extended to ten hours. Fortunately, such long sessions are rarely necessary, but it happens occasionally that, even after three sessions of ten hours (total duration, twelve to thirteen hours), and although the discharge may have ceased for one or two days, the smears and cultures still contain active gonococci. If, in such cases, the duration of the sessions of hyperpyrexia could be prolonged to twelve or even fifteen hours, a cure would still be possible. If, on the contrary, the patient's condition does not permit, or if the patient refuses to submit to such long sessions, the infection continues or returns. We have had such an experience in only three cases.

Action of Fever Therapy on Cardiac Function—

The pulse rate increases rapidly at the beginning of each session of treatment, that is, throughout the phase of rising temperature. Then the pulse rate tends to stabilize itself, but the level of relative stabilization varies considerably. In some cases the pulse rate increases to 120 beats a minute and then oscillates at about this level during the remainder of the session. This is commonly seen in the more or less phlegmatic patient whose nervous system is stable. In other cases the pulse rate increases to 140 or 150 beats a minute and becomes stabilized at this level, in such patients the amplitude of oscillation tends to be greater. This is frequently noted in the patient whose nervous system is unstable and who easily becomes agitated. Between these two extremes there is a wide variation in reaction of the cardiac mechanism. If, during a session of treatment the pulse rate rises to 160 beats a minute, this is regarded as a signal of potential danger and the patient is closely watched. If the pulse rate should exceed 160 beats a minute, the rule is to withdraw the patient from the chamber and terminate the session without further delay, a fresh trial may be attempted two or three days later but, if the pulse does not behave more satisfactorily on the second occasion, further treatment is given up.

This rule, however, is not absolute and is subject to a few exceptions. Even with a pulse rate of 160 beats a minute, certain patients tolerate the treatment well, but when the pulse rate rises to this level or higher, the greatest vigilance must be maintained. Again, it may happen that the normal pulse rate of a patient (before treatment) may be higher than that of the average patient. During a session of hyperpyrexia, with the rectal temperature between 41.1 and 41.7 C (106 and 107 F), the pulse rate of such a patient may be as high as 160 or even 180 beats a minute, without greater danger than in another patient whose pulse rate at the same temperature has become stabilized between 140 and 150 beats a minute. We have had the opportunity to observe this phenomenon in one case, in which, at each of six sessions of treatment the pulse rate rose to and oscillated between 150 and 190 beats a minute. The condition of the patient remained entirely satisfactory, and the infection was rapidly cured.

Fig. 6—The systolic, diastolic and pulse pressure of three patients during a six hour session of hyperpyrexia.

*Action of Fever Therapy on Blood Pressure—*An almost constant observation is that the blood pressure rises more rapidly than the temperature. By this is meant that the pressure begins to rise before the temperature, and this advance continues until the temperature has reached the maximal level at which it is to be maintained. This fact may seem anachronistic but is readily explained by the physiologic adaptation of the body to any increase in temperature. When the body is subjected to a temperature higher than its ordinary temperature, it seeks to dissipate the excess of heat. It matters little whether the increase in body heat is brought about by exposure to external or internal sources of heat, because the body can diminish the excess of heat only by two principal means: cutaneous evaporation through perspiration and pulmonary evaporation through respiration. Therefore, as soon as the body heat begins to increase, even by one degree, the heart begins to function more and more actively, because the heart is then called on to propel the mass of blood more and more rapidly toward the pulmonary

tree and toward the capillary system of the skin. Naturally, this demands a greater and greater activity of the heart as the temperature ascends, but what surprises one at first is the rapidity with which this increase in cardiac function occurs.

During the phase of thermal elevation, that is, during the first hour of each session, the systolic blood pressure increases considerably. As a rule, the systolic pressure increases by 20 to 30 mm of mercury. But after the maximal temperature has been attained, and during the entire period that it is maintained, the systolic pressure gradually falls, hour by hour, so that at the end of a six-hour session the systolic pressure is slightly lower than at the beginning of the session. This drop in systolic pressure generally varies from 10 to 50 mm of mercury. The diastolic pressure, on the contrary, does not rise during the period of thermal ascension but slowly falls throughout the period of hyperpyrexia. In the majority of cases the total fall in diastolic pressure varies from 10 to 35 mm of mercury (fig. 6).

Like the pulse, the reaction of the blood pressure to heat is a matter of individual variation. By itself, the significance of this variation is slight. What is important to know and to watch attentively is the variability of the pulse pressure and pulse rate of each patient, which is to say the differential variations between the systolic and diastolic pressures of the same patient. This is the most accurate index of the condition of the patient and of his ability to tolerate an increase in temperature. If the pulse pressure diminishes, one must be on one's guard, but if the pulse pressure falls to 20 mm of mercury or below, the patient should immediately be withdrawn from the chamber and the session terminated. Such a fall in pulse pressure must be taken as an indication of cardiovascular insufficiency, which should not be prolonged.

COMPLICATIONS

When the treatment is carried out under the conditions and according to the indications and technic that have been given, serious complications of any kind should rarely be encountered. Only slight and insignificant complications are likely to occur. The most common disturbance encountered during or after a session of hyperpyrexia is headache, but since the headache almost always subsides spontaneously within a few hours, special measures to relieve the patient are seldom required. Since the possibility of erythema and the methods of dealing with it have already been mentioned, no further reference to them will be made. In certain cases in which there is a natural tendency to labial herpes, more or less numerous herpetic lesions around the lips may appear after the first session of treatment, but they tend to diminish and to heal spontaneously as the sessions are repeated. They should be treated on general principles.

Nausea and vomiting, which supervene in a small proportion of patients (nearly always women), especially in those who, in spite of strict instructions not to eat any breakfast, have violated this rule, may complicate the treatment by preventing the patient from drinking a sufficient quantity of 0.6 per cent saline solution, which is so essential to compensate for the loss of chlorides and to diminish the weakness which otherwise must inevitably ensue. As has already been pointed out this complication rapidly vanishes after

intravenous injection of 500 or 1,000 cc of a solution containing 10 per cent of dextrose and 1 per cent of sodium chloride. Rarely need the treatment be interrupted on this account.

Another unusual complication, which may occur in a few cases, is muscular tetany of the hands or feet or sometimes even of the abdominal wall. Doubtless, this tetany is an expression of hyperventilation (excessive respiration), because it disappears almost instantaneously when the patient is made to breathe carbon dioxide (5 per cent of carbon dioxide mixed with 95 per cent of oxygen). An intramuscular injection of 10 cc of calcium gluconate is equally effective in most cases, but the effect of carbon dioxide is more certain. In the seventy-six patients treated for gonococcal infection included in this report, muscular tetany occurred only once. In other words, one need not be unduly concerned about it, but when it occurs, it is well to understand its genesis and to act promptly for the well being of the patient.

RESULTS

Between Dec. 1, 1933, and Aug. 1, 1935, ninety-two patients with simple or complicated gonococcal infection were referred for fever therapy. Sixteen of these patients did not receive complete treatment, either

because they failed to cooperate or for other reasons, and must therefore be excluded from further consideration. Of the seventy-six patients²¹ who faithfully completed the treatment, sixty-eight (89.5 per cent) were cured and the condition of seven (9.2 per cent) improved, in only one patient did the infection prove rebellious to treatment. These results would have been even better if some of the patients who were treated early could have been excluded. At that time the only fever chamber available was not air tight and, until the significance of this defect was recognized and the defect was remedied, it was frequently difficult or impossible to raise the patient's temperature sufficiently or to maintain it at a proper level for a sufficient length of time. This partly accounts for the fact that a few patients were not cured until they had received nine, ten, eleven or even twelve sessions of fever. During that period, also, the treatment of some patients was interfered with by factors which we have learned to prevent or to control. With improved technic and greater experience, it is now safe to assume that between 90 and 95 per cent of patients can be cured. The seventy-six patients included in this report received 444 sessions of treatment, or a rough average of six sessions for each patient.

²¹ These include the twenty-nine patients in the cases reported in a previous communication on this subject (J. A. M. A. 104:873-8 [March] 1935).

As may be seen in the table, the majority of patients required six sessions or less. In other words, in fifty-eight cases an average of five sessions of treatment was required to cure the disease permanently. One patient was cured with a single session of treatment. Severe herpes of the lips, mouth, nose and pharynx developed after the first session and further treatment had to be postponed. The patient was confined to bed for nine days, she could not eat, and drinking was difficult. Smears made nine days after the session of treatment failed to show any gonococci, and two cultures made during the succeeding week also were negative. The patient has remained well.

Of the seventy-six patients who completed the treatment, fifty-three were males and twenty-three were females. Thirty-five were married and forty-one were single persons. The shortest duration of the infection in any case had been three days, and the longest duration had been six years, or an average duration of five months. In thirty-six cases the gonococcal infection was confined to the urethra, while in forty cases various complications existed. Five patients had associated pelvic infection, probably of the same kind, although secondary infection may have played a part in the process. Twelve had associated prostatitis, seventeen had gonococcal arthritis as well as urethritis, three had infection of Bartholin's glands, two had epididymitis, one had seminal vesiculitis, four had urethral sinuses, one had periurethritis, one had infection of Skene's glands, one had a prostatic abscess, one had a perimethelial abscess, one had pyelitis, two had cystitis, and one had ureteritis.

As far as complications occurring in the course of the treatment or as a result of it are concerned, thirty-one patients had varying degrees of nausea and vomiting. This occurred in seventeen males and fourteen females but, since the total number of male patients treated was sixty-five while the number of female patients was twenty-seven, the proportion in which nausea and vomiting supervened was 26 per cent for the males and 52 per cent for the females. In three cases the vomitus was slightly streaked with blood, but in associated gastro-intestinal lesion could not be found. The tinge of blood probably resulted from rupture of capillaries in the gastric mucosa from the retching efforts of the patient. Muscular tetany was noted in only one case. Small cutaneous vesicles, without significance, were observed in twenty-four cases, and labial herpes developed in eight cases. Forty-two patients complained of headache after treatment, but this usually subsided within a few hours. Four patients complained of pain in the muscles. It is not yet clear to what factor the muscular pain may have been due.

One male patient had had diabetes for some time when he also contracted a gonococcal urethritis. The diabetes having long been well controlled and the patient being free from other contraindicating disturbances, he was subjected to treatment like any other patient. The first session of fever was followed by a reactive flush, but this subsided rapidly. At the first few sessions the temperature could not be maintained at the required level for a sufficient time, but the subsequent sessions were satisfactory. The urethral discharge did not cease and smears continued to show gonococci until after the seventh session of treatment. If from the very start the required temperature could have been maintained steadily for five or six hours,

it is certain that the number of sessions necessary to effect a cure could have been materially reduced.

Gonococcal Arthritis—The rapidity with which, in a large proportion of cases, the clinical manifestations of gonococcal arthritis subside as a result of fever therapy is astonishing. In the course of the very first session of treatment the pain abates rapidly and the swelling diminishes a little more slowly. When the articular inflammation is acute the effect of fever therapy sometimes is really spectacular. In most cases thorough treatment is followed by complete and permanent resolution of the inflammatory process. When the inflammation is chronic, the clinical manifestations usually abate promptly and the infection is cured. But when the infection has already injured the bones, has already induced reparative changes in the form of connective tissue proliferation or deposition of bone, these as well as the resulting disturbances of function may be favorably influenced to some extent but cannot be expected to disappear completely.

NONSUPPURATIVE ENCEPHALITIS

REPORT OF FIVE CASES

R. J. SHAFER, M.D.

CORNING, N. Y.

Nonsuppurative encephalitis, first described by Barlow and Penrose¹ in 1887, has been comparatively rare until within the last decade. Most of the cases reported have appeared during the past seven or eight years. It has been suggested by Neal and Appelbaum² that the increased incidence of this condition may be due to a greater interest on the part of the physician.

The condition occurs during or following the acute exanthematous diseases, especially measles, dysentery, typhus, pneumonia, influenza, herpes, postvaccinal diseases and exogenous poisons, such as arsenic, lead and alcohol, and recently Winkelmann and Eckel³ reported five cases complicating acute rheumatic fever. Barker⁴ has described the so-called hemorrhagic encephalitis as an acute condition occurring suddenly in previously healthy young persons.

No definite statement can be made concerning the etiology. Actual microbial invasion of the brain has not been found. Levaditi⁵ and Pette⁶ believe the condition is a degenerative process caused by viruses. Globus⁷ holds that it is an inflammatory reaction.

Autopsy reports on the postinfectious forms of encephalitis show distinct gross and microscopic lesions of varying degrees. The leptomeninges show an engorgement of the vessels and considerable fluid in the subarachnoid spaces. There is no mention of any inflammatory exudate over the surface of the brain. In general there is a tendency toward a flattening of

the convolutions with shallow sulci. The cut surface presents a striking appearance. There are hemorrhages, situated mainly in the white matter, which vary in number and size. Some are extensive extravasations destroying much of the brain tissue, while others are tiny punctate hemorrhages. The congestion and hemorrhages give the brain a pink color.

Microscopic examinations of these brains in general show a perivascular hemorrhage about some of the small vessels. The perivascular spaces are infiltrated with cells of the lymphocytic variety. In some of the severe cases there are small areas of hemorrhage. The brain cells do not show any signs of degeneration, except in areas of diffuse hemorrhage. Globus⁷ points out that the so-called areas of demyelination, frequently described, if examined carefully show the adventitial spaces distended with cellular infiltrations, thereby displacing the myelinated fibers and giving the appearance of demyelination. Most observers have reported a glial proliferation, although Globus⁷ believes that many of the cells are lymphocytic rather than glial.

There is a great diversity in the symptomatology in the reported cases. The onset is usually sudden, with such general symptoms as headache, vomiting, confusion, drowsiness, pyrexia, disturbance of the ocular muscles and convulsions. In some of the cases there are hyperesthesia, a spasticity of the muscles and muscular twitchings. There is a stiffness of the neck in most cases. The extremities are either flaccid or spastic and the reflexes variable.

The spinal fluid is clear under normal or increased pressure. The cells are increased and mostly lymphocytes. Globulin and sugar are increased. Cultures and smears are negative.

The blood examination, according to Peterman and Fox,⁸ shows a consistent leukocytosis with a high polymorphonuclears.

I have been able to study five cases of nonsuppurative encephalitis during the past year. Three were associated with measles, one with infection of the upper respiratory tract, and one fatal case in which the etiology was unknown.

REPORT OF CASES

CASE 1—F. E., a boy, aged 14 years, was seized with convulsions three days after the onset of measles, which were followed by apathy deepening into stupor. He was admitted to the hospital Jan. 30, 1935, in a stuporous condition. The examination showed the patient to be acutely ill, convulsive and comatose. The temperature was 105 F. The pulse was 110 and the respiration 28 and heavy. There was a general measles rash over the body. The pupils were small but reacted to light. Intraocular tension was reduced. The heart, lungs and abdomen were normal. There was a double Babinski reflex. The spinal fluid was clear and was under increased pressure. There were 42 cells per cubic millimeter, lymphocytes predominating. There was a moderate increase of globulin. Fehling's reduction for sugar was normal. Smears and cultures were negative for micro-organisms. The Wassermann reaction and Kahn test were negative. Urmalyses were negative. Blood nonprotein nitrogen was 35 mg per hundred cubic centimeters. Blood sugar was 146 mg. No blood counts were made.

January 30 and 31, 10 cc of the father's citrated blood was injected into the patient's buttocks.

The patient made an uneventful recovery and was discharged on the ninth day.

CASE 2—W. B., a boy, aged 11 years, seen March 10, 1935, had begun having measles on the 7th. Three days later menin-

geal symptoms developed. These consisted of frothing at the mouth, rolling of the eyes, convulsions, and fever of 103 F.

When examined, March 10, there was stiffness of the neck and a positive Babinski reflex. The pupils were equal and reacted to light. A distinct measles rash was present.

Lumbar puncture yielded a clear spinal fluid under increased pressure. There were 22 cells per cubic millimeter, mostly lymphocytes. The globulin was moderately increased. Smears and cultures were negative for organisms.

The white blood count was 13,100 per cubic millimeter, with 64 per cent polymorphonuclears. Urine examination was negative.

The following day 20 cc of citrated blood from a boy 7 years old convalescing from measles was given to the patient in the buttocks.

The temperature returned to normal on the third day and the meningeal symptoms gradually subsided. He was discharged from the hospital March 17, completely recovered.

CASE 3—R. T., a girl, aged 14 years, complained of a persistent headache five days after she came down with measles. The following day she was seized with convulsions and then went into deep coma. The examination showed that the patient was acutely ill. The temperature was 104 F., the pulse 128 and the respiration 48 and Cheyne-Stokes in character. She was in a deep stupor and was markedly cyanosed. The neck was rigid. The pupils were dilated and fixed. Kernig's sign was positive. There was a double Babinski reflex and a double ankle clonus. The lungs presented the signs of pulmonary edema. The heart was normal.

Lumbar puncture yielded a clear fluid, which was normal in pressure and contained 100 cells per cubic millimeter, with lymphocytes predominating. There was a moderate increase in globulin, and Fehling's reduction for sugar was normal. Smears and cultures were negative for micro-organisms.

Examination of the blood showed a hemoglobin of 81 per cent. The red blood count was 4,280,000 per cubic millimeter, the white blood count 11,800 with 72 per cent polymorphonuclears.

No treatment was given other than sedatives and the administration of oxygen. At the end of one week she had completely recovered.

These three cases of nonsuppurative encephalitis complicating measles seem to illustrate the typical clinical picture and course. The first two patients were given intramuscular injections of citrated blood. In the third case, which was the most severe, no treatment was given. The group is not large enough to warrant conclusions with regard to the value of citrated blood in the treatment of these cases.

CASE 4—C. B., a white man, aged 64, admitted to the hospital April 11, 1935, complained of a sore throat for five days before his present illness. A few days later he was unable to walk, was drowsy and had a tingling sensation in his finger tips which gradually increased for a period of five or six days until it covered the whole body. Hyperesthesia was marked. He complained of extreme photophobia and dysphagia. The temperature was normal, the pulse 81 and the respiration 16. The blood pressure was 130 systolic, 70 diastolic. Examination showed a drooping of the eyelids. The pupils were equal and reacted to light and in accommodation. There was a slight nystagmus in the extreme external positions and an apparent divergence in the extreme upper position. Diplopia was a persistent symptom. There was no disturbance in speech. His mind was clear but he appeared greatly depressed. There was a marked incoordination in the movements of his arms and legs. The knee jerks were absent. No other abnormal reflexes were noted. The heart and lungs were normal.

The spinal fluid was clear and under normal pressure. There was 1 cell per cubic millimeter. The globulin was slightly increased and Fehling's reduction for sugar was normal. The Wassermann reaction was negative.

There were 5,590,000 red blood cells per cubic millimeter and 14,000 white blood cells, with 58 per cent polymorphonuclears.

⁸ Peterman, M. G. and Fox, M. J. Encephalitis as a Complication of Measles. *Am. J. Dis. Child.* 46: 512 (Sept.) 1933.

The blood Wassermann reaction and Kahn precipitation tests were negative. Roentgen examination of the skull showed no pathologic changes.

Convalescence was slow and the patient was discharged considerably improved April 27.

This case demonstrated a focus of infection in the upper respiratory tract, with neurologic symptoms developing five days after the onset of the infection giving evidence of a diffuse encephalitis.

CASE 5—M. M., a housewife, aged 25, admitted to the hospital May 15, 1935, was about five months pregnant. Her husband stated that when she got up in the morning she was very dizzy and went back to bed. A short time later she was apparently sleeping but could not be aroused. She had been perfectly healthy up to this time and had received no medication.

On examination the patient was in a deep stupor and markedly cyanosed. The throat was filled with mucus and there were signs of pulmonary edema. The temperature was 100 F, the pulse 80 and the respiration 20. The blood pressure was 110 systolic, 60 diastolic. The pupils were dilated and fixed and there was a ptosis of the lids. The knee jerks were absent. There were no other abnormal reflexes. The heart was normal. She never regained consciousness and died on the fourth day. The rectal temperature just before death was 108 F.

The spinal fluid was entirely normal, including a negative culture and Kahn reaction and contained only 4 cells. Blood examination showed 81 per cent hemoglobin, 4,110,000 red blood cells per cubic millimeter and 8,800 white blood cells, with 84 per cent polymorphonuclears. The blood sugar was 125 mg per hundred cubic centimeters, the blood urea 11 mg. The urine was normal except for a trace of sugar.

The autopsy was limited to an examination of the brain, which was normal in size and shape but rather soft. There was a marked congestion of the vessels of the leptomeninges and edema was present. The convolutions were flattened and the sulci shallow. At the base of the brain there was an extensive hemorrhagic exudate. The vessels of the brain showed no evidence of sclerosis. The cut surface showed numerous tiny punctate hemorrhages, which were confined to the white matter.

Microscopic examination showed edema and fibrosis of the meninges, but no cellular infiltration. The blood vessels were congested and dilated. No specific changes were noted in the ganglion cells. The small blood vessels of the cortex were dilated and showed an occasional perivascular infiltration of lymphocytes. The lining cells of the vessels were swollen and there was a tendency toward the presence of vessel groups. There was a moderate gliosis.

This patient, a young adult, although pregnant, had been perfectly healthy up to the time of the present illness. The onset was sudden, with vertigo and rapid loss of consciousness. There was nothing in the physical examination or laboratory studies to indicate the cause of the cerebral symptoms.

At autopsy there were numerous small petechial hemorrhages situated mainly in the white matter of the brain together with congestion of the meninges and the presence of edema.

The pathologic condition suggested a brain reaction as part of a severe toxemia although the origin was undetermined. A diagnosis of acute hemorrhagic encephalitis was made.

SUMMARY

Nonsuppurative encephalitis appears to be a definite clinical entity that has been comparatively rare until within the last decade.

The condition occurs principally as the result of infections or intoxications.

In five clinical cases the observations do not differ essentially from other cases previously reported in the literature.

163 East First Street

RUPTURE OF THE URINARY BLADDER ASSOCIATED WITH PROSTATIC HYPERTROPHY

A. J. SCHOLL, M.D.
LOS ANGELES

Rupture of the urinary bladder occurs rarely, it is usually difficult to recognize and the mortality is still high, even in this period of accurate urologic diagnosis and skilful surgery.

In the early days of surgery many famous physicians were concerned seriously with the study and treatment of rupture of the bladder. Hippocrates¹ stated in his writings that a severe wound of the bladder was deadly. Galen² in later years, commenting on the aphorisms of Hippocrates, states that this term "deadly" meant a very dangerous wound but not necessarily a fatal one. Besley³ states that until the end of the sixteenth century the authority of Hippocrates was so strong that no one would have been bold enough to report a case of recovery. No one expected patients with bladder rupture to recover, and usually they did not. Even up to the time of the elder Larrey,² the famous surgeon of Napoleon's time, the opinion of Hippocrates was universally accepted. Larrey reports that the old grenadiers of the empire, accustomed to be under fire, not troubled with diuresis or incontinence before a battle as were the new conscripts, and even forgetting to empty their bladders in their ardor to fight, were much more commonly seen with ruptured bladders. Other men such as Velpeau,² von Mikulicz,⁴ Dupuytren² and later, in our country, Otis,⁴ Keen⁵ and Ashhurst,⁶ all reported cases or offered suggestions for the relief of a condition that usually resulted in certain death. The English surgeon Syme² was the first (1848) to make a successful surgical intervention for the relief of an intraperitoneal rupture.

ETIOLOGY

The factors usually associated in producing rupture of the bladder are distention, a variable type of trauma, and not infrequently an associated mental or alcoholic incompetence. Cases of bladder rupture are divided into two groups, depending on whether the rupture occurs intraperitoneally or extraperitoneally.

Berndt,⁷ in experiments on cadavers found that rupture caused by intravesical fluid pressure alone most commonly resulted in extraperitoneal tear. In twenty-four cadavers in which rupture was caused by a blow on a full bladder, the rupture was extraperitoneal in nineteen and intraperitoneal in five. Von Dittel,⁸ who carried out a somewhat similar series of experiments, found that when rupture was caused by a simple distention with water, half of the cases ruptured into the peritoneal cavity and the other half extraperitoneally. If distended by air, the rent almost always occurred intraperitoneally.

In a small group of cases, rupture occurs without external violence, usually following distention caused by obstruction to the urinary outflow, in most of these cases there is also an associated disease of the bladder wall. In a number of cases rupture occurred as the result of some interference with the nerve supply of the bladder, namely, a spasmodic or paralytic closure of the bladder outlet. White and Wigram⁹ reported a case of extraperitoneal rupture into the abdominal wall in a patient with complete paralysis of the bladder, and Herting¹⁰ cites three cases of nontraumatic paralytic rupture. Frieberg¹¹ reported a case of intraperitoneal rupture from overdistention without injury in a tabetic patient, 35 liters of fluid was obtained through a catheter inserted urethrally. Regarding paralytic rupture, Morel¹² states that there are two factors working when rupture occurs as a result of paralysis, toleration of the bladder which permits it to dilate, and degeneration of the bladder muscles so that they offer very little resistance to the distention.

In a number of cases rupture occurred directly as a result of some disease of the bladder wall which weakened it. Hedran¹³ reported a case in which spontaneous rupture occurred through an area of fatty degeneration of the bladder wall, autopsy showed that this patient also had a syphilitic aortitis. Castaigne¹⁴ noted a case in which the rupture was through a simple ulcer of the posterior wall. Ludwig¹⁵ described a case of spontaneous perforation through the bladder wall in an area occupied by a papillary tumor. Crosbie¹⁶ reported a spontaneous case through a bladder wall weakened by an infiltrating carcinoma. In a case of Bitschar's,¹⁰ in which there was a tumor in the base of the bladder, a perforation occurred through the upper posterior wall into the peritoneal cavity. There was no bladder muscle at the site of perforation, the area having been replaced by inflammatory connective tissue. Goldenberg¹⁷ reported two cases in which the sudden muscular compression of the abdominal muscles resulting from lifting heavy objects caused intraperitoneal ruptures. Mailland¹⁸ described a case of rupture secondary to pressure necrosis of the bladder wall from a uterine fibroma. Chattaway¹⁹ reported the case of a woman four months pregnant who had a spontaneous intraperitoneal bladder rupture following forty-eight hours of urinary retention, 1 gallon of urine was removed from the abdominal cavity.

In some cases rupture, while not caused by external trauma or violence is nevertheless the result of influences outside the bladder itself and is not in the true sense a spontaneous occurrence. Such may occasionally follow diagnostic and therapeutic procedures on

the bladder. Rupture has not infrequently occurred from overdistention during a cystoscopy, general and spinal are not as safe as sacral anesthesia for these cases, because in sacral anesthesia the pain sense from overdistention is not completely lost. Wagner²⁰ reports six cases of rupture after the injection of fluids into the bladder, and Neve²¹ noted that rupture occurred following the injection of only 270 cc of fluid preparatory to doing a litholapaxy. Cassuto²² described a case in which rupture of the bladder resulted from an intravesical explosion of the gases accumulated from fulguration of the bladder neck. Saint Cene,²³ who reported two analogous cases, found that the explosion took place on fulgurating near the upper surfaces of the bladder where gas accumulates. Kietschmer²⁴ recently reported two cases of intravesical explosion with rupture of the bladder during transurethral electroresection of the prostate.

Occasionally a case is described in which rupture seems to be the result of mechanical obstruction alone. King⁴ reports a case of bladder rupture occurring in a fetus with an imperforate urethra, and Sisk²⁵ quotes a case of Talbot's in which rupture occurred as a result of unrelied phimosis. Rather exceptionally rupture of the bladder is seen in association with stricture of the urethra or prostatic obstruction. In both these conditions there is usually an associated cystitis and a degeneration of the musculature of the bladder wall. Sisk² reported a case of spontaneous extraperitoneal rupture of the bladder as a result of obstruction to the urinary outflow by a urethral stricture that had been present since childhood. Similar cases have been reported by Lejar² and Besley.³

Cases in which rupture of the bladder occurred in association with prostatic hypertrophy are very rare, but references to such conditions are occasionally seen in the literature. Rupture in such cases is primarily due to obstruction at the bladder neck and secondarily increased intravesical pressure, plus degenerative changes in the bladder wall. Moser²⁶ reports the case of a man aged 59, in whom rupture occurred as a result of long-standing dilatation of the bladder caused by hypertrophy of the prostate.

The following case is one in which prostatic obstruction caused a chronic distention of the bladder, cystitis, disease of the bladder wall and, finally, a rupture into the extraperitoneal tissues.

REPORT OF CASE

A man, aged 76, had been having difficulty in urination during the last three years. There was frequency and nocturia every hour, and it was usually necessary to strain considerably to empty the bladder even partially. He had had some dribbling for a year, but during the last six months there had been a gradually increasing incontinence, for the last three months he passed no urine except that which dribbled out. During this time he was in bed most of the time and found it necessary to make some effort to force out a little urine every hour or two during the day or night. Seven days before admission he had as he expressed it a gripe in the abdomen since which

time he had had constant abdominal pain and tenderness and a mass in the lower part of the abdomen which gradually increased in size and was at this time the size of a grapefruit. He had been catheterized only once, shortly before coming to the hospital.

On entry into the hospital the temperature was 96 F, the pulse 84 and the blood pressure 120 systolic and 70 diastolic. The pupils reacted normally and the other reflexes were not unusual. He was in moderate shock but roused readily when questioned. The lungs were clear and the heart regular, with faint sounds and no murmur. The arteries were tortuous and sclerosed but compressible. The bladder was markedly distended and on the abdominal wall above the pubes a hard rounded, nonfluctuant fixed mass, about 8 cm in diameter could be felt. After catheterization of the bladder the mass was slightly less prominent and more freely movable but apparently did not diminish in size. Thirty ounces (887 cc.) of cloudy, foul-smelling urine was removed with the catheter. The catheter was fastened into the urethra and left in place. The prostate was about twice the normal size, firm, fixed and rounded but not irregular or exceptionally hard.

The urine contained a large amount of pus, blood and albumin, but no sugar. An examination of the blood showed a hemoglobin of 48 per cent, and each millimeter of blood contained 3,200,000 red blood cells and 21,000 leukocytes, 83 per cent of which were polymorpho nuclear cells. Roentgen examination of the kidneys, ureters and bladder revealed nothing unusual except an area of increased density in the region of the suprapubic mass. A Wassermann test on the blood was negative.

Two conditions presented themselves for consideration—a cystic formation of the lower end of the urachus or a ruptured bladder. The latter diagnosis seemed substantiated by the long history of urinary difficulty, the sudden onset of the tumor and the bladder neck obstruction. The patient was in moderate shock and the urinary retention was satisfactorily relieved by the indwelling urethral catheter, consequently only a simple incision and drainage of the mass appeared to be necessary. The patient was taken to the operating room and, under a local anesthetic a midline incision was made in the suprapubic mass. Between the muscles and the overlying fascia there was a collection of about 4 ounces (118 cc.) of foul, highly infected urine. The area was drained and the wound closed loosely. The bladder was not exposed and no urine was seen oozing into the wound as the bladder was kept empty by means of the urethral catheter. As the patient was somewhat in shock nothing further was done. He recovered rapidly from the operation and several days later the two hour intravenously injected phenolsulfonphthalein was 15 per cent 5 per cent the first hour and 10 per cent the second five days after this it was 25 per cent for the two-hour period. The wound healed readily, and the patient's general condition became improved. An electrocardiogram showed indications of myocardial changes and gave a suggestion of generalized arteriosclerosis.

Cysto urethroscopy revealed an enlargement of the lateral lobes of the prostate (2 on a scale of 1 to 4) together with an enlarged middle lobe. The bladder wall was markedly trabeculated and there were many small cellules. In the anterior upper wall of the bladder there was an area of inflammation about 2 cm in diameter in the center of which were several linear tears or scars.

As the patient did not readily tolerate a permanent urethral catheter it was removed after a few days and suprapubic drainage was instituted under a local anesthetic. The skin and fascia were cut and the muscles retracted. The peritoneum and structures overlying the bladder were matted down, thickened adherent and friable but stripped from the surface of the bladder without much difficulty. No evidence was found of an open urachus or of anything resembling the urachus. The tract through which the bladder had opened into the overlying tissues could be readily made out, but no fluid was coming through at this time. The bladder wall was very friable and at least 1 cm thick. It was incised with a knife

and a No 30 Pezzer tube fixed in place. Exploration of the bladder revealed nothing unusual but the enlarged prostate.

The bladder was closed and the patient made a good operative recovery. He left the hospital two weeks later to go home, the suprapubic tube being still in place. He returned one month later for prostatectomy.

DIAGNOSIS

Patients with traumatic bladder rupture generally have severe pain in the lower part of the abdomen at the time of injury. This pain is continuous and is associated with vesical tenesmus, and usually the patient is in moderate shock. The symptoms in cases of spontaneous rupture differ very little from those in which rupture is caused by trauma. Spontaneous rupture is more likely to occur in elderly individuals with a history of prolonged bladder trouble. Generally in cases of rupture there is a strong desire but inability to urinate, or only a few drops of blood may pass. In some cases voiding may be quite free, the urine being blood tinged. Besley noted that the patient is usually unable to walk.

Rupture of bladder wall opening into extraperitoneal tissues

or does so with difficulty and that at the time of injury there is a sense of something giving way or tearing in the lower part of the abdomen.

If the rupture is extraperitoneal there is usually pain and swelling in the suprapubic area, and there may be signs of extravasation such as brawny edema or pitting of the tissues. The patient becomes septic and at times has chills and fever. Intraperitoneal ruptures, which, unfortunately are the more common type, are more serious and at times quite difficult to recognize. Symptoms of peritonitis, such as abdominal tenderness and muscular rigidity, appear early, and later vomiting and obstipation. On the other hand, a number of cases of intraperitoneal rupture have been reported in which the abdominal cavity was filled with urine for several days without signs of peritonitis.

In early reports of cases the catheter test and the injection test are frequently mentioned. These tests are still used quite as a routine and at times may be of value. The patient may be catheterized and no urine or only a small amount of bloody urine obtained, or possibly an amount is withdrawn much greater than

could be contained in a bladder of normal size. No urine or a large amount of urine from an individual who has not voided for a considerable time is added evidence of rupture of the bladder. The bladder opening may have permitted the urine to escape into the peritoneal cavity, from which it cannot be withdrawn, or there may be such a large tear in the bladder wall that a free flow back and forth is possible. In some cases extremely large amounts may be withdrawn, Freiberg drained off more than 3 liters by catheter. In the injection test a measured amount of solution is injected into the bladder and then withdrawn, a smaller or larger return suggesting either a loss or a gain in fluid through an opening in the wall.

Cystoscopy in some cases is of little value on account of inability to distend and fill the bladder with fluid, or visualization may be decreased by extensive bleeding. Mathe²⁷ states that small tears may be overlooked with the cystoscope, as the tear usually does not extend straight through the bladder wall, like an incision made by the scalpel, but extends in and on different planes between the muscle layers.

Cystography, following the simple injection of a medium opaque to x-rays, will usually give definite and accurate information as to the condition present. Roentgenography, following the injection of air after removal of most of the opaque medium from the bladder, gives a good contrast picture, usually indicating the condition of the bladder, the location and, at times, the extent of the lesion present. Mark,²⁸ observing the innocuousness of mediums for intravenous urography, has used this medium in a case of extraperitoneal rupture of the bladder, being able not only to diagnose the condition correctly but to note accurately the location of the lesion. This procedure, while useful in some cases, is of little value in the presence of shock, as the medium is not readily excreted by the kidneys.

TREATMENT

The treatment in both the intraperitoneal and the extraperitoneal types of rupture is usually immediate operation. This condition is a surgical emergency, and delay, particularly when rupture into the peritoneal cavity has occurred, is as dangerous as in the case of any other acute abdominal lesion. When the tear has been through the peritoneum the abdomen is opened, the bulk of the fluid is withdrawn by suction and the rent in the bladder is closed. Both the peritoneal cavity and the bladder are then adequately drained. In some cases, as shown by Crosbie,¹⁶ if the bladder tear is small it need not be sutured, as it will close itself when proper drainage of the bladder is provided. In the extraperitoneal type of rupture the main procedure is bladder drainage, together with drainage of any perivesical pockets or areas of extravasation. Usually individuals with rupture of the bladder are in poor general condition, and rapid accurate operation is necessary only what is absolutely essential at that time being done.

MORTALITY

The mortality even of uncomplicated rupture of the bladder, always has been and still is very high. Complications and coincidental injuries in the traumatic cases greatly increase the severity of the condition.

Bartels⁹ in 1878 reported a mortality of 96 per cent in ninety-eight patients treated without operation.

27. Mathe C. P. Traumatic Rupture of the Bladder. *California & West Med.* 42: 384-385 (May) 1935.
28. Mark E. G. Intravenous Urography in the Diagnosis of Rupture of the Bladder. *J. A. M. A.* 100: 42 (Jan. 7) 1933.
29. Bartels M. Die Traumen der Harnblase. *Arch. f. Klin. Chir.* 22: 519-628 and 715-1878.

Rivington³⁰ in 1884 collected 300 cases, thirty-eight patients recovered, of which number thirty were in the smaller group of extraperitoneal ruptures. Although the other eight were described as being intraperitoneal cases, Rivington questions the diagnosis, believing them also to be extraperitoneal in type. This illustrates the attitude at that time toward the extreme rarity of recovery in cases of intraperitoneal rupture. Seldowitsch³¹ in 1904 reviewed thirty-four cases from the Russian literature. Twenty-eight (87.5 per cent) ended fatally. Also fifteen patients who were not operated on died. In the same year Dambrin and Papin³² in France collected and analyzed seventy-eight cases in which operation was done for intraperitoneal rupture, thirty-four (43.5 per cent) of the patients died. Thirty-four patients of this series had been operated on since 1895, of these only seven (23 per cent) died. Negley³³ in 1927 reviewed thirty-four cases from the Los Angeles General Hospital. Fourteen cases were of extraperitoneal rupture, four patients died, a mortality of 28.6 per cent. There were twenty cases of intraperitoneal rupture, four patients died, a mortality of 20 per cent. In 1929 Campbell³⁴ reported fifty-five cases from Bellevue Hospital, thirty-five (63.6 per cent) patients died. Of the patients suffering from intraperitoneal involvement, twenty-six (73.5 per cent) died, only nine (42.9 per cent) of those with extraperitoneal involvement died.

Besley³⁵ stated in 1907: "No one condition seems better to illustrate the advances that have been made in modern surgical work than the results now obtained in the treatment of rupture of the bladder." In the early days of surgery almost all patients died. The abdomen was not opened without fear of peritonitis, and consequently many patients were not operated on. The associated lesions and complications took their toll and all in all, rupture of the bladder was a very serious condition. Since Besley made his statement, progress in surgery has been much better illustrated by operative results on organs other than the bladder. The present mortality, while still very high, is mainly due to the tremendous shock and the coincidental lesions, conditions placing the patient beyond help when first seen. In only a small part is the high mortality now due to delayed or unskilful procedures. In uncomplicated cases, when operation is early, the prognosis, both for intraperitoneal and for extraperitoneal rupture of the bladder, should be fairly good.

Deformed Bones in Spite of Vitamin D—Normal bones can be formed only when the food contains ample amounts of calcium and phosphorus. In the case of a lesser supply either vitamin D or ultraviolet light is capable of preventing the occurrence of rickets, but normal bone will not form. It will always contain less than the normal per cent of calcium phosphate. If the dietary calcium or phosphorus is sharply restricted deformed easily fractured bones will result in spite of large intakes of the vitamin—Newburgh L. H., and MacKinnon, Frances. *The Practice of Dietetics*, New York, Macmillan Company, 1934.

Clinical Notes, Suggestions and New Instruments

PARALYSIS OF THE AXILLARY (CIRCUMFLEX) NERVE WITH SPONTANEOUS RECOVERY AFTER SEVEN MONTHS

SIDNEY HIRSCH, M.D., NEW YORK

Senior Clinical Surgical Assistant to the Mount Sinai Hospital,
New York. Surgical Adjunct, Trinity Hospital, Brooklyn

The unusual etiology of paralysis of the axillary (circumflex) nerve with the resultant clinical problems prompts me to report this case.

The exposed position of the axillary nerve in its winding course around the outer aspect of the humerus makes it particularly liable to injury. It can easily be torn or compressed

Fig. 1—Roentgen appearance immediately after accident showing comminuted stellate fracture of the right scapula and fracture of the acromial end of the clavicle. The line below the head of the humerus is the natural epiphyseal line.

may be accomplished by the supraspinatus muscle. There is also loss of sensation over the cutaneous distribution of the nerve involving the skin over the long head of the triceps and lower posterior part of the deltoid. The arm is held in adduction by the unopposed pectoralis major, the latissimus dorsi and the subscapularis muscles.

ANATOMY

The circumflex nerve arises from the posterior cord of the brachial plexus and consists of fibers from the dorsal divisions of the fifth and sixth cervical nerves. It passes downward and outward behind the third portion of the axillary artery and over the outer border of the subscapularis muscle to enter the quadrilateral space together with the posterior circumflex artery and vein, which lie above the nerve. It then turns about the posterior and external surface of the surgical neck of the humerus to end within the deltoid muscle.

The nerve consists of two main bundles, the larger medial funiculus supplying the teres minor and a part of the spinal portion of the deltoid after which it passes under the deltoid and around the lower part of the posterior border to supply the skin over the long head of the triceps and the lower two thirds of the posterior part of the deltoid. The lateral branch gives off the articular branch to the shoulder joint and supplies the remaining portions of the deltoid.

REPORT OF CASE

I, G., a well developed girl aged 14 years, was accidentally thrown off her horse, Oct. 20, 1934, and was unconscious for a few moments. I saw her one half hour after the accident when a physical examination revealed exquisite tenderness over the acromial end of the right clavicle and tenderness and bony crepitus over the right scapula.

I did not attempt to lift her right shoulder nor did I ask the patient to do it.

The diagnosis was fracture of the right clavicle and comminuted fracture of the right scapula.

This diagnosis was verified by roentgen studies (fig. 1). Since the fragments were in excellent position I applied a simple Velpeau bandage for immobilization. At the end of two weeks I commenced baking and massage. At the end of the third week I began mild passive motion. At the end of the fifth week I discovered that attempts at active abduction of the shoulder were futile and that passive abduction beyond 60 degrees caused pain. I ascribed the limitation of motion to the pain and this in turn to the fracture. Check up roentgenograms revealed good healing with the fragments well approximated and with no excessive callus (fig. 2). At the end of the seventh week, when attempts at active abduction were still unsuccessful, I investigated further. I found that there was some atrophy of the right deltoid muscle, the roundness of the shoulder having disappeared, causing undue prominence of the acromion and coracoid processes. There was also flattening in the outer infrascapular region.

Sensory examination showed complete anesthesia to pin prick and moderate degrees of temperature over the cutaneous distribution of the fifth and sixth cervical branches comprising the axillary nerve, with a somewhat wider area of anesthesia to cotton wool (fig. 3).

Electrical stimulation showed absent response of the deltoid muscle to faradic current with definite though sluggish response to galvanic current. No attempt was made to determine reaction difference to anodal or cathodal polar closure.

All this information proved the absence of axillary nerve conductivity. The arm was immediately placed in a cast with abduction to about 100 degrees, the forearm pointing upward. Sinusoidal treatment with gentle massage to the deltoid region was begun and given every second day. At the same time the shoulder joint was kept supple by manipulation and movement above the 90 degree angle.

By February 1935 there were still no signs of sensory or motor improvement. An orthopedic consultant felt that sufficient time had been allowed for conservative therapy. Since there was no improvement he urgently favored exploration. He stated that in spite of the surgical difficulties involved in exposing the axillary nerve it gave the patient her only hope for restoration. He was not sure in what part of the nerve's course he would find the loss of continuity, but he felt that the best exposure would be at its emergence from the quadrilateral space before it winds about the humerus.

A neurologic consultant felt that although we had waited the customary four months for evidences of regeneration he would still wait an additional two to three months. The type of injury, a blow and not an incised wound and the absence of any fracture of the neck or shaft of the humerus prompted this attitude. In addition, there was some deep muscle tenderness which he felt was a definite indication of the presence of some nerve conductivity. He also knew of a large number of cases in which no evidences of regeneration were shown for eight or nine months after injury and which then went on to recovery. He felt that the maintenance of circulation and nutrition of the paralyzed muscles by continuous massage and electricity would offset the bad effect of a long interval between injury and operation if operation ever had to be done.

It was the type of case in which it was impossible to make certain that the nerve had actually been divided and that the

Fig. 2—Roentgen appearance Nov. 19, 1934, about four weeks after the accident showing excellent healing.

various sensory and motor changes were not due to concussion or partial laceration from which a recovery might still be expected. I definitely felt, together with the neurologist, that operation was only hazardous and could more than justifiably be delayed.

The passage of another two months bore out the wisdom of the conservative attitude. There was definite evidence of

Fig 3—A area of anesthesia to pin prick moderate degrees of temperature and cotton wool. B additional area of anesthesia to cotton wool.

sensory return by a shrinking of the area of anesthesia to pin prick, cotton wool and changes of temperature.

In April 1935 the sensory anesthesia was only one half the original, although there was still no evidence of motor return. Motion is generally much later in its restoration than sensation. At this time contrast (hot and cold) applications to the deltoid region were begun and continued as a bi-daily treatment in addition to the other measures.

About May 15 seven months after the original injury, it was observed that the patient was able actively to abduct her shoulder. About this time the area of anesthesia to cotton wool had completely disappeared that to pin prick had

only a few very small areas of disturbed but not absent sensation and that to hot and cold testing had recovered about 90 per cent.

At this writing, July, there is no remaining disturbance of sensation. The muscle tone of the deltoid has improved considerably and the patient is able actively to abduct the shoulder completely. She is still wearing the airplane brace and is still receiving the treatment.

DERMATITIS OF THE PENIS CAUSED BY EPHEDRINE

JESTER HOLLANDER, M.D., PITTSBURGH

Instances of sensitivity to ephedrine have been noted previously, and the occurrence itself would be unworthy of report. The fact of a curiously distant localized sensitivity and the manner by which the irritating substance reached the affected area may be of sufficient interest to warrant recording the following case.

K. K., aged 42, consulted me Sept. 10, 1934, on account of a swelling and redness of the prepuce and the under surface of the shaft of the penis. On a somewhat elongated area of the anterior and under surface of the penis, a few discrete vesicles were discernible. The patient was most uncomfortable because of the itching and burning and on account of the difficulty that he experienced during micturition, the intense edema interfering with the passage of the urine. The condition was of one week's duration and it was steadily getting worse.

The usual causes producing a contact dermatitis in this location, such as contraceptives containing quinine, condoms and chemicals (saponated solution of cresol) used as vaginal disinfectants, were inquired for, but there was no history of the use of these or the exposure to them.

The patient was put to bed and a greatly diluted solution of aluminum acetate dressing was applied. The inflammation subsided readily as a result of this treatment.

A few days later, however, the previous symptoms recurred with great severity. Questioning elicited the fact that the patient was using a hair preparation containing quinine, and I accepted this as the most likely agent causing the sensitivity, the irritant reaching the affected part through the medium of the fingers. The presence of the small discrete vesicles on the under surface of the anterior part of the penis, where the organ is held during urination, strengthened this hypothesis. Patch testing on the arm gave entirely negative results.

Reemployment of the previous treatment again yielded good results. When the inflammation had totally subsided, treatment was discontinued and the patient was instructed to wash his hands thoroughly before urination.

No further trouble was experienced until Sept. 8, 1935, when the patient reappeared for examination with the same eruption in the same location. This time the coincidence of the season of the year was noted and his history was retaken, which brought out the fact that he was subject to early fall hay fever. This was missed entirely on previous questioning as the patient had had only a mild attack of hay fever.

In going into the question of medication of his hay fever it was found that he was using an ephedrine nasal spray quite frequently, and also that he had long discontinued to wash his hands before urination.

After the dermatitis of the penis had totally disappeared a patch test of the ephedrine spray was applied to the arm with completely negative results. Then a 1:50 dilution of the ephedrine nasal preparation was sprayed on the penis, creating an intense reaction and thus proving the local sensitivity, which was somewhat baffling for a time.

This case illustrates

1. A local sensitivity that cannot be proved with patch testing unless the test is applied directly to a previously affected area.

2. That strict attention must be paid to a history of all factors involved; the causative agent was missed one year before because of failure to inquire regarding hay fever and its treatment.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE
HOWARD A. CARTER, Secretary

GOULD NEGATIVE ION PROCESS NOT ACCEPTABLE

Manufacturer: Gould Negative Ion Company, Boston

The company claims that the negative ion process is an atmospheric electrical treatment, and is unlike any other kind of electrical therapy.

The following description of the negative ion process as produced with the Gould apparatus is copied from a booklet distributed by the firm:

Ozone is formed and reacts with unsaturated molecules of a special grade of oil which produces an ozonide aldehyde.

Positive ions are removed by means of a negative voltage potential. The air containing negative ions is driven onto the surface of the oil by a power driven fan which fixes the negative ions on neutral molecules. Thus there are ozonide aldehyde vapors, free negative ions and negative ions fixed on neutral oil molecules which are flowing from the vaporizing chamber to the organism being treated.

A positive voltage potential is placed on the body, the negative end of the circuit being connected to a part of the apparatus. Thus the organism becomes the anode and the apparatus the cathode of a circuit composed in part of the flow of negative ions from the vaporizer. The placing of the positive voltage potential on the body causes it to become selective to the negative ions which are electrostatically attracted. Its purpose is also to separate the negative ion from the neutral molecule.

The negative ion upon being detached from the molecule enters the organism and flows towards the positive voltage potential. The position of the positive potential on the organism seems to have a marked effect on the results obtained. Clothing and especially silk will extract the ions to a certain extent thus preventing their entry into the body. Accordingly the practice should be to have the patient disrobe as much as possible and avoid silk in any form.

To obtain the best results from the process the patient should be treated from one to not more than two hours.

Many therapeutic claims are made for the Gould Negative Ion Process. Some of these claims appear in the following excerpts from the company's advertising matter:

The blood is affected in all diseases. This process revitalizes the blood stream; it charges the blood with a normal supply of oxygen thereby allowing the Red Blood Cells and the Hemoglobin to form its natural combination with oxygen which increases the oxidation activity of the blood stream. The White Cells will return to normal faster than the Red Cells.

After a few treatments by this process the general physical condition of the patient is noticeably improved. It stimulates the action of the intestine resulting in more regular evacuations.

The process is harmless; it consists of visible vapor (not a medicine) that kills contagious and infectious germs.

PARTIAL LIST of Diseases Treated—This process has proven successful in treating Asthma and all respiratory diseases, Hypertension, Sinusitis, Rheumatism, Varicose Ulcer, Pyorrhea, Vincent's Angina, Chronic Constipation, Nervous Disorders, some Skin Diseases and Arthritis. It gives almost immediate relief to sufferers from Hay Fever and the relief lasts throughout the season.

Critical or convincing evidence to substantiate the aforementioned therapeutic claims has not been made available to the Council on Physical Therapy. In the opinion of the Council, promotional literature of this kind constitutes an appeal to the public with arguments that have not been verified and may harmfully enhance the feeling of false security on the part of the persons acquiring the device and making use of the process.

In view of the lack of evidence to substantiate the claims made for the Gould Negative Ion Process and until the Council on Physical Therapy voted not to include the process and unit in its list of accepted devices.

JUNIOR BOVIE ELECTRO SURGICAL AND MEDICAL DIATHERMY UNIT ACCEPTABLE

Manufacturer—The Liebel-Flarsheim Company, Cincinnati.

This unit is designed for electrosurgery but it may also be used for medical diathermy. Three types of current are available: cutting, coagulating and medical diathermy. It is provided with convenient switches making these currents readily accessible. The power required to operate the machine at full load is approximately 300 watts. Its wavelength is about 600 meters. Figure 2 is a diagram of the circuit.

Fig. 1—Junior Bovie Electro Surgical and Medical Diathermy Unit

Evidence was submitted pertaining to the electrical and physical characteristics of the unit. The data showed that the temperature rises of the transformer and spark gap were within the limits adopted by the Council. An examination of the electrical circuit and the parts by the Council's investigator indicated that good material had been employed in the manufacture of this unit and the machine assembled in a workmanlike manner. Its shipping weight is unit 89 pounds; subcabinet 60 pounds.

The performance of the apparatus was satisfactory when used for seven months in a clinic acceptable to the Council under the conditions for which it is recommended.

Fig. 2—Schematic diagram of circuit

In view of the favorable report the Council voted to include the Junior Bovie Electro Surgical and Medical Diathermy Unit in its list of accepted devices.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary

DOLE BRAND HAWAIIAN PINEAPPLE NATURAL UNSWEETENED SLICED (PACKED IN UNSWEETENED JUICE)

Manufacturer—Hawaiian Pineapple Company, Ltd., San Francisco.

Description—Peeled, cored and sliced Hawaiian pineapple, processed and packed in undiluted pineapple juice.

Manufacture—The method of manufacture is essentially the same as for Dole 1 Hawaiian canned pineapple slices (THE JOURNAL, April 8, 1933, p. 1106) except that unsweetened juice is used to fill the cans.

Analysis (submitted by manufacturer) —	per cent
Moisture	83.5
Total solids	16.5
Ash	0.5
Fat (ether extract)	0.02
Protein (N X 6.25)	0.4
Reducing sugars as invert sugar	6.3
Sucrose	7.7
Crude fiber	0.3
Carbohydrates other than crude fiber (by difference)	14.4
Titrate acidity as citric acid	0.9

Calories—0.6 per gram, 17 per ounce.

Vitamins—Biologic assay shows canned pineapple to contain vitamin A and to be a good source of vitamins B and C. Practically equivalent to the fresh fruit in A and B, slightly inferior in C.

Claims of Manufacturer—Fancy grade canned sliced pineapple representing fruit most uniform in color, flavor, texture and workmanship. Packed in undiluted pineapple juice without added sugar. The canned product is practically equivalent to the fresh fruit in nutritional values (vitamin C slightly reduced).

CLLU BRAND TOMATOES WATER PACKED

Distributor—Chicago Dietetic Supply House, Inc., Chicago.

Packer—L. H. Schlecht, Rossville, Ill.

Description—Canned whole peeled tomatoes, packed in water.

Manufacture—Selected tomatoes are washed, inspected, sorted, scalded, hand peeled and packed in cans. The cans are filled with water, heated, sealed and processed.

Analysis (submitted by distributor) —	per cent
Moisture	94.6
Total solids	5.4
Ash	0.5
Fat (ether extract)	0.4
Protein (N X 6.25)	0.8
Crude fiber	0.5
Starch (dia tae method)	2.4
Carbohydrates other than crude fiber (by difference)	2.2

Calories—0.2 per gram, 6 per ounce.

Claims of Manufacturer—Choice quality whole tomatoes packed without added sugar or salt. For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

MARCO BRAND EVAPORATED MILK

Distributor—H. A. Marr Grocery Company, Denver, Lind, Okla., Omaha, Amarillo, Texas, Colorado Springs, Colo., Sterling, Colo., Plainview, Texas, Pampa, Texas, Clovis, N. M.

Packer—Carnation Milk Products Company, Milwaukee, or other manufacturers of accepted evaporated milks.

Description—Canned unsweetened sterilized evaporated milk the same as Carnation Milk (THE JOURNAL, June 14, 1930, p. 1919).

RECENT STUDIES ON POLIOMYELITIS

The second portion of an article on poliomyelitis, written by Biraud and Deutschman¹ and published in the Epidemiologic Report of the Health Section of the Secretariat of the League of Nations, summarizes recent additions to knowledge concerning this disease. The antigenic properties of poliomyelitis virus, they say, differentiate it clearly from the bacteria and identify it with the ultraviruses. Further evidence of the ultravirus nature of the etiologic agent is its ability to cause the appearance of inclusions in the nerve cells it attacks. The monkey remains the best experimental animal for the study of the behavior of poliomyelitis virus. From investigations on this animal it appears that the virus follows the nerve fibers as do the rabies virus and that of yellow fever.

Immunity to poliomyelitis has been the subject of numerous recent studies. The extreme rarity of second attacks is evidence of the immunizing nature of this condition. The immunity, however, is not stable, at least at the beginning, since relapses are not prevented and are sometimes brought about by intercurrent diseases. Neither does the immunity imply the immediate disappearance of the virus, as is shown by the recuperation of the virus after cataphoresis of the nervous center of the monkey twelve days after recovery from poliomyelitis. It is even possible that this persistence of the virus helps to strengthen immunity. The titration of the neutralizing antibodies in serum has given much additional immunologic information. Thus, when the serums of twenty-three persons who had been in close contact with poliomyelitis were tested, twelve did not neutralize the virus, but five months later when six of these were retested they all possessed neutralizing power. Furthermore, eight of fifteen subjects whose contact with patients had been occasional proved non-immune immediately and the six retested three and a half months later gave the same result. Unapparent

infection therefore causes immunity to develop at only a slow rate.

A review of the geographic location of poliomyelitis indicated that epidemics and characteristic sporadic cases are indubitably more frequent in countries with cold or temperate climates. The disease is not excluded, however, from warm countries, and the lower numbers of cases notified in tropical countries can no doubt be explained partly by the less well developed medical organizations often present. Whatever the explanation, a reason has not yet been found for the fact that the proportion of imperceptible infections, as measured by the neutralizing antibodies, is higher in warm than in temperate or cold countries.

The value of serum treatment of poliomyelitis is difficult to analyze. The practical impossibility of diagnosis before the onset of the paralytic stage, the normally low number of cases of paralysis in the average untreated epidemic, and the difficulty of obtaining adequate control all militate against easy conclusions with regard to the effectiveness of serum treatment. The authors summarize the present position of this question as follows: "1. Experimental studies show that the most active serums are powerless to check the development of the disease even when given before the onset of the initial febrile stage. 2. In the absence of strict control groups and owing to the impossibility of foreseeing the course of preparalytic cases, there are no irrefutable statistical proofs of the efficacy of the serum, even when applied at the preparalytic stage. Inversely, there is no absolute proof of its complete ineffectiveness. 3. The majority of observers have reported favorable clinical effects from the use of serum (decline of symptoms of intoxication and of fever, etc.), these effects often being apparent immediately, whatever the mode of administration (intracerebral, intraspinal, intramuscular or intravenous)."

Two methods of prophylaxis have received the most concentrated study. Thus the prophylactic use of convalescent or immunized animal serum, and of immunotransfusion, is based on experimental results that have generally been favorable but have not yet received convincing statistical proof of its efficacy for man. Even if effective, however, the immunizing action cannot be prolonged or repeated indefinitely. Hence, prophylaxis by vaccination has been attempted on a fairly wide scale.

The virus used in vaccination has been variously killed or attenuated by solutions such as formaldehyde or sodium ricinoleate. Administration of such vaccines has usually resulted in considerable immunity developing. The authors state, however, "that vaccination against poliomyelitis is now practicable without serious risks and with considerable probability of effectiveness." The report of Leake² was evidently unknown at the time these words were written. Current opinion

¹ Biraud and Deutschman. Poliomyelitis. History of the Disease and of Research Concerning Its Epidemiology During Recent Years. Epidemiologic Report. Health Section of Secretariat League of Nations 14: 207 (Oct-Dec) 1935.

² Leake, J. P. Poliomyelitis Following Vaccination Against This Disease. J. A. M. A. 105: 2152 (Dec. 28) 1935.

since Leake's report of twelve cases of polyomyelitis following vaccination tends definitely to consider vaccination at present too dangerous to employ. Furthermore, some obscurity exists on another point. If, as some evidence indicates, polyomyelitis assumes its paralytic form in persons whose constitution makes them unable to produce antibodies in sufficient quantity, the effectiveness of vaccination in such cases is doubtful a priori. If the latter hypothesis is true, the persons successfully vaccinated would be precisely those in whom the infection would have manifested itself in unapparent or abortive forms in any case.

While great progress has undoubtedly been made in the understanding of polyomyelitis, effective control must await further fundamental elucidation.

ROLE OF BILE IN VITAMIN A UTILIZATION

Much evidence is available emphasizing the role of bile in the absorption of lipids,¹ little or none of this foodstuff is absorbed when bile is excluded from the intestinal tract. This decreased absorption of the lipids is significant first with respect to the requirement of the organism for this material for purposes of energy. It assumes added importance when considered from the point of view of water-insoluble substances that depend on fat as a vehicle for transport across the intestinal wall. Decreased absorption of cholesterol, for example, has been noted in icteric patients and is apparently associated with a diminished absorption of fat. Whether the bile aids the absorption of cholesterol by direct solvent action on this sterol or by an indirect assistance through its effect on fat (a solvent for cholesterol) is not entirely clear. The fact remains that bile influences the absorption of lipids and of materials associated in nature with this class of substances.

One of the most important fat soluble substances of physiologic interest is vitamin A. It seems logical to reason a priori, therefore, that bile should play an important part in the absorption of vitamin A or its precursor, beta carotene, from the intestinal tract. Interesting laboratory and clinical evidence has recently been offered to support this hypothesis and to emphasize the important influence of bile in the utilization of vitamin A.

The laboratory contributions of Schmidt and his co-workers² at the University of California have presented suggestive observations on the absorption of fat soluble vitamin A in the absence of bile and have pointed out quite unexpected differences in the ability of icteric animals to utilize the vitamin as contrasted to its precursor beta carotene. Using the rat as the experimental animal, and employing the daily vaginal smear examination as a criterion of vitamin A deple-

tion, these investigators found that the absorption of vitamin A, in the form of cod liver oil, from the gastro-intestinal tract does occur in the absence of bile. In experimental icteric rats on low vitamin A diets, it was possible to restore the normal vaginal smear pictures by oral administration of cod liver oil. The storage of vitamin A in these animals could then again be depleted to a level at which only cornified cells, indicative of restricted vitamin A intake, were found in the vaginal smears. It was then possible to restore the normal picture for the second time by oral administration of cod liver oil. In contrast to these results with the oil, it was observed that in the absence of bile the vitamin A deficient rat does not respond to oral administration of a mixture of the alpha and beta carotenes. The carotene therapy did cause a positive response in these animals, however, when the material was given by subcutaneous injection. Further evidence of the important role of the bile acids as carriers of carotene across the intestinal wall of the rat was provided by the demonstration that the vitamin precursor is effective orally in icteric rats if the substance is administered together with preparations of the bile acids.

Although it is difficult to analyze case reports in the early literature because of the lack of dietary data, it seems evident that there has long been a clinical association of severe protracted jaundice with various manifestations of what is now known as vitamin A deficiency. Within recent years the specific connection between hepatic disease with icterus and vitamin A deficiency has become definitely apparent. The importance of this relation may be emphasized in view of the possible role of bile in the absorption of vitamin A. In spite of the fact that the diet received may be adequate in vitamin A and lead to none of the more obvious manifestations resulting from a lack of this vitamin, recent reports indicate that more deep-seated changes, evident only at necropsy, may be occurring. Altschule³ has presented an interesting postmortem study of eleven infants with congenital atresia of the bile ducts. All these infants received diets adequate in respect to vitamin A, and none presented clinical evidence of xerosis or keratomalacia during life. However, definite microscopic evidence of vitamin A deficiency was found in six of the eleven cases. It seems possible that in the clinic also this deficiency may be related to a failure of absorption of vitamin A or its precursors from the intestinal tract as the result of the absence of bile. The presence of this deficiency disease may be overlooked because the consequent gross manifestations, as specific ocular changes occur much later than the histologic alterations. The experimental and clinical data indicate the efficacy of parenteral administration of vitamin A in conditions of severe obstructive jaundice. Oral administration, accompanied by bile salts, may also be of value.

EXPERIMENTAL AND CLINICAL SINUSITIS

Since 1930 Fenton and Laisell have carried on a series of investigations on sinus inflammations. Their studies have been made for the most part by observing the effects of surface applications to the membranes of the frontal sinus in cats. These membranes were first inflamed by inoculation with human strains of hemolytic streptococci. In a communication now appearing¹ these studies have been summarized. A number of preparations have been employed including histamine, azochloramide aminoacetic acid, acetylcholine amniotic fluid isotonic chlorophyll, sodium alum and ten new compounds thought to have effects similar to those of ephedrine. Some of these substances have been tried also on patients. The investigators were forced to conclude from these studies that, owing to the defensive factors inherent in sinus epithelium and the connective tissue elements of its tunica propria almost every preparation applied to the surface of such membranes becomes an irritant unless its strength is isotonic. Stronger solutions are almost certain irritants, as are those which in any way interfere with ciliary action, no matter how well they may function as antiseptics in a test tube. Only a few chemical substances are favorable to the growth of cells and stimulate an influx of reparative histiocytes and leukocytes. It has also been demonstrated that histiocytes take up particulate matter from the outer (bony) side of the sinus membrane as well as from the lumen of the cavity. Specifically, histamine in the normal sinus merely increases the flow of mucus but in repeated doses causes severe acute exacerbation of chronic suppuration. Azochloramide was shown to share the irritant properties of similar substances without stimulation of repair. Reparative effects were also not noted after the application of aminoacetic acid or acetylcholine to the surface, although the latter brought about marked edema of both the acutely and chronically infected membranes. Amniotic fluid both half and full strength caused marked congestion leukocytic infiltration and early fibrous reparative changes with diminution of the superficial destructive changes during seventy-two hours. Astringents (sodium alum and tannic acid) used in weak solution inhibited greatly the severity of infection when such sinuses were subsequently inoculated. The new ephedrine-like compounds had a slightly stimulating effect toward repair, especially tetrandine methiodide. All produced slight blanching and shrinking of human mucous membrane. Proof of excessive fibrosis caused by roentgen therapy was afforded by the examination of the tissues from a man so treated. The authors feel that little is to be gained at present from further histopathologic study of sinus membranes of cats treated by local applications. The anatomic problems of lymphatic drainage of the sinuses however, and of their anatomic innervation remain unsolved. Although difficult these problems are of much importance in the interpretation of the physiology and pathology of the sinuses.

1 Fenton R A and Laisell Olof Research Report on Experimental and Clinical Sinusitis Arch Otolaryng 23 18 (Jan) 1936

DEATH RATE FROM ALCOHOLISM

Probably the best evidence of the extent of alcoholism can be obtained from comparative examinations of deaths due directly to this cause. Leary¹ has recently reported deaths accredited to alcohol in Suffolk County, Mass., from 1913 to 1934. Most of the deaths were directly due to alcoholism as such. The added cases included a percentage of the alcoholic pneumonias in which the alcoholic factor was of primary importance and some of the cases of fractured skull in which the degree of alcoholism was responsible for the injury that led to the fracture. The list did not include deaths from automobile accidents of any kind. The criteria have not changed to any appreciable degree in the period recorded. The deaths related to alcoholism were on a relatively standard average basis in the years 1913, 1914 and 1915. In 1916 and 1917 there were considerably more deaths. These were years of prosperity when workers were well paid. In 1917 and 1919 under the influence of patriotic urge we became one of the most temperate people in the world, with a corresponding drop in the number of alcoholic deaths. Then came prohibition with little liquor available in 1920 and a still further drop in the deaths from alcohol. In the following two years a rise again began. The deaths during this period were for the most part in those who had access to bathing alcohol, bay rum, perfumes and Jamaica ginger. By 1923 the bootlegging business was well established and the sources of supply were many. The alcohol deaths continued to rise under this influence until 1925 after which they continued at a fairly high but slightly downward level until 1933. Prohibition was abolished Dec 4, 1933. In Massachusetts the local alcohol control system permitted the sale over the counter by druggists of 95 per cent alcohol. During the year ended Dec 4, 1934, there was a tremendous rise in the alcohol death rate. By contrast with the lowered death rate reported elsewhere the probability is indicated that the sale of concentrated alcohol is largely responsible. Since concentration as well as quantity is a known factor there seems little doubt that the readiness with which ethyl alcohol can be purchased over the counter in drug stores is an important element in the increase reported.

PRODUCTION OF CASEIN

Ordinarily casein is considered in connection with the nutritive value of milk and cheese, there is approximately 2.5 per cent of this important protein in fluid cow's milk. In the commonly used varieties of cheese, from 20 to 35 per cent is casein and the products of its digestion. However, casein enters into commerce widely in other ways than as a food. In the form of a colloidal solution in alkali, it is used as glue, cement or putty. When chalk, clay or kaolin is added to the thin casein glue a size or coating for paper is obtained. Dry powdered casein or moist curd when heated becomes plastic and in this condition can be pressed or molded into any desired shape. This material can be turned cut and polished and enters into commerce as artificial ivory, artificial celluloid, artificial cork and mitting and

1 Leary Timothy The Death Rate from Alcoholism New England J Med 214 15 (Jan 2) 1936

as imitation leather. Paints are made from casein in alkali with a suitable filler and pigment, the protein finds use in the dyeing and textile industry as an absorbent and a loading agent. Heretofore large quantities of casein have been imported from South America, New Zealand and Australia, two thirds of that used in 1920 and one half of that used in 1929 being obtained from foreign countries. According to a recent report¹ by 1934 only 4 per cent of the casein used was imported. In that year 37,331,000 pounds was produced domestically. It is obvious from these figures that the United States is rapidly becoming self sufficient in respect to the production of this important product of the dairy industry.

Association News

THE KANSAS CITY SESSION

Section Headquarters

The Hotel President has been selected as the hotel headquarters for the Section on Obstetrics, Gynecology and Abdominal Surgery at the annual session of the American Medical Association to be held in Kansas City in May. All accommodations are under the supervision of Dr. Ira H. Lockwood, chairman of the Housing Committee, who may be addressed in care of the Chamber of Commerce, 1028 Baltimore Avenue, Kansas City, Mo. Requests for reservations should be sent to Dr. Lockwood as soon as possible.

Fraternity Luncheons

Reservations for fraternity luncheons for Wednesday noon May 13, have been made as follows:

Hotel Baltimore: Phi Chi, Dr. Ralph E. Duncan, chairman; Hotel Kansas City: Alpha Mu Psi, Omega, Dr. Pat Dunn, chairman; Omega Upsilon Phi, Drs. C. K. Smith and John Bouslog, chairmen; Phi Alpha Sigma, Dr. E. P. Heller, chairman; Phi Beta Psi, Dr. Orville Withers, chairman; Theta Kappa Psi, Dr. Herluf Lund, chairman; Hotel Muehlebach: Phi Delta Epsilon, Dr. L. M. Shapiro, chairman.

Hotel President: Alpha Epsilon Iota, Dr. Lorraine Sherwood, chairman; Alpha Kappa Kappa, Dr. David Braden, chairman; Nu Sigma Nu, Dr. E. H. Hershinger, chairman; Phi Rho Sigma, Dr. Ralph Perry, chairman.

Fraternities desiring reservations may communicate with Dr. Harry M. Gilkey, 1316 Professional Building, Kansas City, Mo.

RADIO BROADCASTS

The American Medical Association broadcasts over WEAF the Red network instead of the Blue as formerly, and certain additional stations of the National Broadcasting Company at 5 p. m. eastern standard time (4 o'clock central standard time, 3 o'clock mountain time, 2 o'clock Pacific time) each Tuesday, presenting a dramatized program with incidental music under the general theme of 'Medical Emergencies and How They Are Met'. The title of the program is 'Your Health'. The program is recognizable by a musical salutation through which the voice of the announcer offers the toast: 'Ladies and gentlemen, your health!'. The theme of the program is repeated each week in the opening announcement which informs the listener that the same medical knowledge and the same doctors that are mobilized for the meeting of grave medical emergencies are available in every community day and night for the promotion of the health of the people. Each program will include a brief talk dealing with the central theme of the individual broadcast.

Red Network—The stations on the Red network of the National Broadcasting Company are WEAF, WEEI, WTIC, WJAR, WTAG, WCSH, KXW, WFBR, WRC, WGY, WBF, WCAE, WTAM, WWI, WMAQ, KSD, WHO, WOW, WDAF.

Pacific Network—The stations on the Pacific network are KGO, KPO, KFI, KGW, KOMO, KHQ, KFSD, KTAR.

Network programs are broadcast locally or rejected at the discretion of the local station. The lists indicate stations to which programs are available.

The next three programs are as follows:

March 3: Cancer, W. W. Bauer, M.D.
March 10: Hard of Hearing, Morris F. Hahn, M.D.
March 17: Eyesight Saving, W. W. Bauer, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS REFLECT TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Bust of Lincoln Presented—A bust of Abraham Lincoln, presented to the Los Angeles County Medical Association by Dr. Sven R. Lokrantz, was unveiled at a meeting, February 20. The program included an address by the sculptor, David Edstrom, and one by Mr. H. A. Guernev, pilot United Air Lines, entitled 'Behind the Scenes of Air Transportation'. Dr. Harlan Shoemaker, president of the association, also spoke.

The Eyesight Swindlers Again—Sheriff Rayburn of Riverside reported January 2 that two swindlers using the 'radium water eye drop racket' had been paid \$75 by an elderly person in his vicinity for their services. One man used the name A. C. Mueller. He was said to be about 45 years of age, 6 feet tall, weighing 185 pounds, with dark hair and eyes. The other, John Doe Reed, was about 50 years of age, 5 feet 9 inches tall and weighed about 150 pounds. He was of slim build with dark hair and eyes and wore glasses. He had a thin face and hollow cheeks.

Society News—The San Bernardino County Medical Society devoted its meeting in San Bernardino, January 7, to a symposium on cancer of the breast. Speakers included Drs. John M. Plude, Los Angeles, western field representative of the American Society for the Control of Cancer, Carlos G. Hilliard, Redlands, John A. Patterson, Colton, C. Owen and Philip M. Savage, Sr., San Bernardino, Calvert L. Emmons, Ontario, and John G. Stanb Jr., Redlands. Dr. Samuel Hanson, Stockton, addressed the San Joaquin County Medical Society, January 9, on 'Occurrence and Management of Persistent Occiput Posterior', and Dr. Edmund W. Butler, San Francisco, 'Aid to Diagnosis in Wounds in the Abdomen' and 'Recent Advances in the Treatment of Poisons'. At a meeting of the Sonoma County Medical Society in Vallejo, January 14, Dr. Hym Lissner, San Francisco, spoke on 'Adrenal Cortical Syndromes with Mention of Cushing's Disease, and Arrhenoblastoma'. Dr. Edward B. Shaw, San Francisco, discussed communicable diseases before the Sonoma County Medical Society in Santa Rosa, January 9.

DISTRICT OF COLUMBIA

Medical Bills in Congress—S. 3514 has passed the Senate, proposing to regulate the manufacture, dispensing, sale and possession of narcotic drugs in the District of Columbia. H. R. 8437 has passed the Senate directing the Commission on Licensure to Practice the Healing Art in the District of Columbia to issue a license to practice medicine to Dr. Arthur B. Walker.

FLORIDA

Personal—Dr. Paul G. Shell, Marianna, health officer of Jackson County, has resigned to accept a similar position with the health unit in Duval County; he will be succeeded by Dr. Frank V. Chappell, medical officer of Jacksonville.

Society News—At a meeting of the Pinellas County Medical Society in St. Petersburg, January 3, the speakers were Drs. John A. Hardenbergh on 'The Heart During Pregnancy', Albert R. Frederick on 'Addison's Disease', and Norval M. Marr on 'Electrocardiographic Observation'. The society was addressed February 7 by Drs. Wiman W. Harden on 'Some Phases of Gynecology of Interest to General Practitioners', William E. Queksall on 'Treatment of Otitis Media in Children', and George Lochner on 'Medical Ethics in Review'. At a meeting of the Duval County Medical Society in Jacksonville, January 7, Dr. Harry B. McEuen discussed 'Carcinoma of the Larynx' and Dr. Irving J. Strumpf, 'Pneumonia in Pregnancy'.

GEORGIA

Accidental Deaths—Deaths from accidents in Georgia showed an increase of 20.2 per cent during the ten year period 1925-1934, with automobiles heading the list of causes according to the state health department. In 1934 there were 2,251 accidental deaths, of which automobiles were responsible for 802 including fatalities from collisions of automobiles with other vehicles. The deaths attributed to automobiles alone totaled 644 in 1934, as compared with 348 in 1925.

ILLINOIS

Society News—At a meeting of the Henry County Medical Society in Cambridge February 13, Dr Ford K. Hick, Chicago, discussed pneumonia and Dr Charles M. McKenna, Chicago, prostaticitis. Dr Harry E. Mock, Chicago, discussed skull fractures before the Whiteside County Medical Society in Sterling, February 20. Dr James H. Hutton, Chicago, addressed the Champaign County Medical Society, February 13, on 'Gland Therapy and Hypertension'. At a meeting of the La Salle County Medical Society in Mendota January 30 Carlos I. Reed, Ph.D., and Dr Carroll W. Stuart, both of Chicago, discussed "Concentrated Vitamin D in Treatment of Arthritis and 'Diseases of the Mouth and Their Relation to Systemic Disease' respectively.

Chicago

Clinical Meeting—The Institute of Traumatic Surgery will hold an all day clinic session at St. Luke's Hospital, March 15, commencing at 9 a. m. Cases will be presented in the morning. The guest speaker in the afternoon will be Dr Roger Anderson, Seattle, who will discuss "Ambulatory Methods of Treating Fractures of the Shaft of the Femur and Functional Method of Treating Fractures of the Shaft of the Humerus." A dinner in honor of Dr Anderson will be held at the Palmer House in the evening.

Society News—Dr Jerome R. Head, among others, addressed the Chicago Pediatric Society, February 18, on "Posture in the Etiology, Prophylaxis and Treatment of Diseases of the Lung." Dr Alfred J. Kobak discussed 'Maternal Deaths from Abortion in 1934' before a meeting of the maternal welfare committee of the Chicago Gynecological Society, February 18. Speakers before the Chicago Gynecological Society, February 21, included Drs Garwood C. Richardson on "Significance of the Fetal Heart Tones and Uterine Firmness in Abruptio Placentae," Clyde J. Geiger, 'Benign and Malignant Polyps of the Cervix Uteri' and Marshall W. Field 'Spontaneously Occurring Painless Labor in the Absence of Neurologic Diseases'.

Ambulances to Be Equipped with First Aid Splints—An ordinance has been passed by the city council requiring all ambulances to be equipped with first aid and splint appliances. Funds for this purpose are to be expended by the police, fire and health departments. Supplies are to be obtained from funds in the present budget and the personnel will be trained by the physicians of the various departments. Men are to be selected for this work and a sufficient number trained to make them adept and to supply at least one for each vehicle equipped. The equipment will include half-ring Thomas leg and half-ring Thomas arm splints, a few muslin bandages and some adhesive tape. The splints are to be kept in a small bag suspended from the side or top of each vehicle. The plan was originally sponsored by Dr Kellogg Speed.

IOWA

Personal—A dinner was recently given by the Greene County Medical Association in honor of Drs William M. Young, Jefferson, who has practiced fifty-three years, Benjamin C. Hamilton, Jefferson, fifty-two years, and John H. Shipley, Rippey, forty-seven years.

Society News—Dr Maurice C. Hennessy, Council Bluffs, among others, addressed the Cass County Medical Society in Atlantic January 10, on 'The Social Security Act as It Affects the Medical Profession'. Dr John F. Noble, St. Paul, discussed 'Heterophile Antipneumococcus Serum Therapy in Lobar Pneumonia' before the Cerro Gordo County Medical Society in Mason City, January 21. Among others, Dr John A. Thorson, Dubuque, addressed the Clayton County Medical Society in Elkader, January 7, on 'The Management of Sinusitis in Children'. Speakers before the Crawford County Medical Society in Denison January 14 were Drs Anthony L. Fink, Carroll, on 'Ambulatory Treatment of Diseases of the Rectum' and Raymond C. Scannell, Vail, 'Peptic Ulcer and Its Treatment'. A symposium on arterio-

sclerosis and cardiovascular renal disease was presented before the Dubuque County Medical Society January 14, in Dubuque by Drs Frank P. McNamara, Henry G. Langworthy, Laurence E. Cooley and Walter Cary. Dr Lee R. Woodward, Mason City, discussed "The Anemias" before the Hardin County Medical Society in Eldora, January 21. Speakers before the Pottawattamie County Medical Society in Council Bluffs, January 27, were Drs Arnold L. Jensen, "Bilateral Emphysema in a Child", Jack V. Treynor, "Chronic Labyrinthitis," and Aldis A. Johnson, "Diverticulitis." Dr Howard L. Beye, Iowa City, discussed conditions requiring surgery following cholecystectomy.

KANSAS

Cancer Control Program—The committee on the control of cancer of the Kansas Medical Society will sponsor a program throughout the state, March 31-April 4. Scientific sessions will be held in the afternoon for members of the state society and their guests, and public meetings in the evening. No admission will be charged. Speakers will be Drs Burton T. Simpson, director, State Institute for the Study of Malignant Diseases, Buffalo, Charles F. Geschickter, head of the department of surgical pathology, Johns Hopkins University, Baltimore, and Frank L. Rector, Evanston, Ill., field representative American Society for the Control of Cancer. These sessions will be held in Chanute March 30, Wichita March 31, Dodge City April 1, Hays April 2, Salina April 3, and Topeka April 4.

LOUISIANA

Society News—The Seventh District Medical Society was addressed in Opelousas, December 12, by Drs Bernard G. Efron, on management of asthmatic symptoms, Arthur Neal Owens, plastic surgery, and Curtis H. Tyrone, diagnosis of early carcinoma of the cervix. All were from New Orleans. Dr Hillard E. Miller presented a case of hydatid cyst of the uterus before the Orleans Parish Medical Society, February 10. Drs Walter E. Levy and Harry Meyer presented an Analysis of the Touro Infirmary's Obstetrical Service for the Year 1935 Based on a New Record System, and Drs Abraham L. Levin and Morris Shushan, a paper on "Value of the X-Rays in the Interpretation of Gastro-Intestinal Disease." The society recently adopted resolutions to sponsor a safety campaign.

MASSACHUSETTS

New Professor of Biological Chemistry—Dr Cyrus H. Fiske, since 1929 associate professor of biochemistry at Harvard Medical School Boston has been appointed professor. Dr Fiske graduated in medicine at Harvard in 1914. After one year as assistant at his alma mater, he served at Western Reserve University School of Medicine, Cleveland, until 1918 when he returned to Harvard.

Anniversary Volume in Honor of Dr Christian—At the regular clinical pathologic conference in the Peter Bent Brigham Hospital Boston February 17, Dr Henry A. Christian, physician-in-chief at the institution was presented with a volume of medical papers dedicated to him by his former students, colleagues and house officers, as a token of affection on his sixtieth birthday. The presentation was made by Dr Francis G. Blake, Sterling professor of medicine Yale University School of Medicine, New Haven. The volume contains 1,000 pages of papers on many phases of internal medicine. About half of the articles represent original research. The few copies available may be obtained from Dr Robert T. Monroe at the Peter Bent Brigham Hospital. Dr Christian is also Hersey professor of the theory and practice of physic at Harvard Medical School.

Course in Automobile Control to Reduce Accidents—Regular graduate courses on automobile traffic control will be started next fall by the Harvard University bureau for street traffic research in a scientific attack on automobile accidents. The New York Times reported January 21. This is said to be the first move along this line by any university. Fifteen fellowships of \$1,200 each will be awarded to college graduates interested in traffic control engineering. In the announcement of the plan it was said that the current loss of life and the serious social and economic consequences of the traffic problem make it one of national importance and certainly one which is a very proper subject for university research and professional training. College graduates not more than 35 years old are eligible. Those now holding positions in fields related to street traffic control will be accepted on a leave of absence basis so that they may return to their positions after the period of study Sept. 28, 1936 to June 18, 1937. Each fellowship will have extra provision up to \$200 for travel and field expense, it was stated.

MICHIGAN

Dr Doan Will Give Beaumont Lectures—Dr Charles A Doan, professor of medicine and director of research, Ohio State University College of Medicine, Columbus, will deliver the Beaumont Lectures for 1936 at the Institute of Arts March 23-24. The illustrated lectures will be on 'The Histopathology of the Blood'. The series is sponsored by the Wayne County Medical Society.

Society News—Dr Charles H. Peckham, associate professor of obstetrics, Johns Hopkins University School of Medicine, Baltimore, addressed the Wayne County Medical Society, February 3, under the auspices of the Detroit Obstetrical and Gynecological Society, his subject was 'The Incidence, Differential Diagnosis and Immediate and Remote Prognosis of the Toxemias of Late Pregnancies'.—Dr Lowell S. Selling, Detroit, discussed 'The Doctor Looks at Crime' and Judge John V. Brennan 'Criminology' at a meeting of the West Side Medical Society, Detroit, in January.—Dr Sanford R. Gifford, Chicago, discussed treatment of detachment of the retina before the Detroit Ophthalmological Society, February 5.—Dr John R. Birch presented a paper before the Detroit Otolaryngological Society, January 15 on 'Laryngeal Obstruction'.—Dr Hans A. Jarre exhibited a new method of irradiating the petrous apex and nasal sinuses.—Dr Clarence A. Neymann, Chicago, discussed 'Psychoanalysis and Its Application to the New Neuroses and Psychoses' before the Calhoun County Medical Society, Battle Creek, February 4.—Dr Albert C. Furstenberg, Ann Arbor, will address the society, March 3 on 'Acute Infection of the Throat and Soft Tissues of the Neck'.—Dr Louis F. Foster, Bay City, was elected chairman of secretaries of county medical societies at the annual secretaries' conference in Lansing, January 26.

MISSOURI

University News—Washington University School of Medicine, St. Louis, offers a week's intensive training in ophthalmology and otolaryngology, March 2-7. Only qualified specialists in these fields will be accepted. Information may be had from the dean of the school.

Bill Introduced—S. 292 proposes (1) to authorize the insurance commissioner to license any person, firm, association or corporation to engage in the business of a hospital service association or corporation, or the business of making contracts in advance of sickness or illness, to furnish or pay for hospitalization and (2) to exempt such licensees from the provisions of the insurance laws.

Physicians Honored—Tribute was paid to three physicians at a dinner recently given by the staff of the Independence Sanatorium, Independence, in honor of their many years of practice in the community. The three physicians were Drs. Oliver C. Shelev, who has practiced forty-six years in Independence, Calvin Atkins, thirty years, and William E. Messenger, twenty-eight years, according to newspaper accounts. Dr. Charles F. Grabske, president of the sanatorium, presided and speakers included William Southern Jr., editor of the Independence *Examiner*.

Lectureship in Honor of Dr. Loeb—A lectureship has been established by the Mu chapter of the Phi Beta Pi Medical Fraternity in honor of Dr. Leo Loeb, Edward Mallinckrodt professor of pathology, Washington University School of Medicine, St. Louis. Under the Leo Loeb Lectureship, medical scientists of distinction will be invited each year to address the students and faculty of the school; the lectures to be open to all members of the university and to the medical public. The first lecture will be given early in March. Dr. Loeb graduated from the University of Zurich Faculty of Medicine. He has been associated with Washington University since 1915 and has been professor of pathology since 1924. From 1910 to 1912, Dr. Loeb was chairman of the Section on Pathology and Physiology of the American Medical Association.

Medicomilitary Symposium—The Spring Medicomilitary Symposium will be held at the Municipal Auditorium in Kansas City, March 9-10, under the direction of Col. Kent Nelson, seventh corps area surgeon, and Lieut. Comdr. Lincoln Humphreys, representing the surgeon general of the navy. The morning sessions will be devoted to twenty-minute addresses by clinicians of Greater Kansas City; the afternoons will be given to two clinic periods followed by instruction periods for reserve officers of the army and navy. The evenings will be divided between clinical lectures and military addresses. Guest speakers will include Dr. Ernest Sachs, professor of clinical neurologic surgery, Washington University School of Medicine, St. Louis, on 'Classification and Management of Head Injuries', and Dr. Edward F. Roberts, New York, who will present

motion pictures on 'Management of Pneumonia' and 'Pernicious Anemia: Diagnosis, Treatment and Results'. Programs in surgical technique are being arranged by Dr. Max Goldman at several hospitals for Wednesday. The symposium is open to all regular physicians; no fee will be charged.

NEW JERSEY

Society News—Dr. Henry A. Rafsky, New York, addressed the Bayonne Medical Society, January 20, on 'Non-surgical Treatment of Pyloric Obstruction as a Result of Peptic Ulcer'.—Dr. Israel Strauss, New York, addressed the Bergen County Medical Society, Hackensack, February 11, on 'Neurologic Signs and Symptoms for the General Practitioner'.—Dr. David M. Davis, Philadelphia, addressed the Atlantic County Medical Society, Atlantic City, February 14, on 'Prostatic obstruction'.—Dr. Ernest A. Spiegel, Philadelphia, addressed the Academy of Medicine of Northern New Jersey, Newark, January 14, on 'Convulsive Disorders'.—Dr. Carl Eggers, New York, discussed 'Surgical Conditions of the Stomach' before the Hudson County Medical Society, Jersey City, February 4.

Bills Introduced—A. 158 to amend the workmen's compensation act, proposes that no physician employed in the Department of Labor or by the State Rehabilitation Commission shall during his employment accept or participate in any fee from any insurance company authorized to write workmen's compensation insurance or from any self-insurer, whether such employment or fee relates to a workmen's compensation claim or not. A. 180 proposes in effect, that the statute of limitations shall not start to run against a patient on any claim or right of action he may have against a physician for malpractice until such time as the patient has knowledge of the injury alleged to have been inflicted on him by his physician. A. 185 to amend the workmen's compensation act, proposes to make it easier for employees to recover compensation for hernias allegedly due to employment. The bill proposes that where there is traumatic hernia resulting from the application of force directly to the abdominal wall, either puncturing or tearing the wall, compensation will be allowed. In all other cases compensation will be allowed when there is a preponderance of proof that the hernia was caused by such sudden effort or severe strain (1) that the descent of the hernia followed within twenty-four hours of the cause, (2) that there was severe pain in the hernial region, (3) that the employee was compelled to cease work within twenty-four hours, (4) that the condition was of such severity that it was noticed by the workman and communicated to the employer within forty-eight hours after the occurrence of the hernia, (5) that there was such physical distress that the attendance of a licensed physician was required within forty-eight hours after the occurrence of the hernia. A. 195, to supplement the pharmacy practice act, proposes to authorize the courts, on the application of the board of pharmacy, to restrain the unlicensed practice of pharmacy or other violations of the act. A. 395 proposes to authorize the sexual sterilization of certain socially inadequate persons, whether inmates of state institutions or not.

NEW YORK

New School Health Director—Hiram A. Jones, Ph.D., director of physical education in the state department of education for the past four years, has been appointed director of school health and physical education, having made the highest rating in a civil service examination. Dr. Jones, 36 years old, is a graduate of Allegheny College, Meadville, Pa., and received the degree of doctor of philosophy from Columbia University. He will have charge of health and physical education activities in schools throughout the state.

Augustus Downing Dies—Augustus S. Downing, LL.D., for many years an official of the New York State Education Department, died at his home in Albany, February 5, aged 79. In his capacity as assistant state commissioner of education and director of professional education, Dr. Downing was active in obtaining the passage of the state medical practice act. According to the *Albany Times Union*, the law was defeated in the legislature thirteen times before it was enacted in 1926. Dr. Downing was made deputy commissioner of education and in 1927 he retired from active work. Several colleges had conferred honorary degrees on him.

Committee to Study Suicide—The 'Committee for the Study of Suicides' was recently chartered in Albany by a group of psychiatrists and others to conduct research into causes and possible prevention of self-destruction. Dr. Gerald R. Jamieson, clinical director of Bloomingdale Hospital, White Plains, is president. Mr. Marshall Field, New York, vice president, and Dr. Gregory Zilboorg, New York, secretary and

director of research. Other members are Drs Franklin G Lbaugh, Denver, Henry Alsop Riley, Dudley D Shoenfeld, Herman Nunberg and Bettina Warburg, all of New York, Miss Elizabeth G Brockett, social worker, New York, and Mr Barklie McKee Henry, president of the Association for Improving the Condition of the Poor, New York.

Bills Introduced—S 898 proposes to create a state board of opticians and to regulate the practice of opticians. The bill defines as an optician "a person who holds himself out as being able to produce or reproduce optical instruments, or one who deals in optical instruments or eyeglasses prescribed for the treatment, improvement or correction of the vision, or who can reproduce or duplicate existing lenses of any character of the same foci in any form, who is skilled in the science of optics, treating with the nature and properties of light and vision, and who deals in optical instruments, eyeglasses and essential parts thereof. Superintends grinding of lenses for eyeglasses to precise geometrical form to correct visual abnormalities of the human eye and possesses the ability and skill to make accurate eye, facial measurements adapted in fitting and adjusting the eyeglasses as prescribed by the eye physician, known as oculist or optometrist or duly licensed optometrist for the treatment, improvement and corrective effect of vision." S 918 and A 1134 propose that the provisions of the pharmacy practice act shall not apply to the sale of drugs, medicines, chemicals, prescriptions or poisons at wholesale when not for the use or consumption of the purchaser provided, however, that no manufacturer or wholesaler may sell any drug, medicine, chemical, prescription or poison containing poisonous, deleterious and/or habit forming drugs to any person or corporation unless such person or corporation has been duly authorized to sell such drug, medicine, chemical prescription or poison at retail." S 988 and A 1170 propose to grant to charitable and to governmental hospitals treating persons injured through the negligence of others liens on any judgments, awards, compromises or settlements accruing to the injured persons because of their injuries.

New York City

Annual Art Exhibit—The New York Physicians Art Club will hold its annual exhibit, April 4-18 at the New York Academy of Medicine. Exhibits must be delivered at the academy before March 14. Checks for \$6 made out to Dr Winfred Morgan Hartshorn for the 1936 assessment must be mailed to Dr Louis C Schroeder, 50 East Seventy-Second Street, secretary of the club.

Society News—Dr Leonard Greenburg of the division of industrial hygiene, state department of labor, Albany, addressed the Bronx County Medical Society, February 19, on "Industrial Diseases and Their Relation to the New Compensation Law."—Drs William Edward Chamberlain, Philadelphia, and William P Healy addressed the Medical Society of the County of Kings, February 18, on "Radiation Therapy in Cancer" and "Deep X-Ray Therapy in Pelvic Neoplasms," respectively.

Program on Effects of Noise—The Medical Society of the County of New York devoted its meeting February 24 to consideration of the effects of noise on health. Dr Edmund Prince Fowler discussed the effects of noise on the normal and the abnormal ear, Dr John L Rice, health commissioner and Dr Sigismund S Goldwater, commissioner of hospitals, the effect on public health. Dr Foster Kennedy, the effect from the neurologic point of view. Harvey Fletcher, Ph.D. of the Bell Telephone Laboratories presented a demonstration of various noises showing their loudness in decibels.

Friday Afternoon Lectures—The Medical Society of the County of Kings announces the following lectures in its Friday afternoon series:

Dr Leonard G Rowntree Philadelphia Relationship of the Thymus and Pineal Gland March 6
Dr Hugh H Young, Baltimore The Prostate March 13
Elmer V McCollum Sc D Baltimore Vitamins March 20
Dr Louis E Phaneuf Boston Gonorrhea Its Partial Abortive and Tuberculous Pelvic Infection—Its Prevention and Treatment March 27
Dr Rela Schick Childhood Tuberculosis April 3
Dr Russell M Wilder Rochester, Minn, spoke on Hypoglycemia February 28

Professor of Psychiatry Appointed—Dr Oskar A Diethelm, associate psychiatrist at Johns Hopkins Hospital Baltimore has been appointed professor of psychiatry at Cornell University Medical College and psychiatrist in chief to New York Hospital to succeed Dr George S Amsden, who retired in 1935. Dr Diethelm who is 38 years old was born in Switzerland and was graduated in medicine from the University of Zurich Faculty of Medicine in 1922. He went to Johns

Hopkins in 1925 as house officer in the Phipps Psychiatric Clinic and two years later was appointed resident psychiatrist. In 1932 he was appointed associate professor of psychiatry at Johns Hopkins University School of Medicine.

OHIO

Society News—At a meeting of the Toledo Academy of Medicine, February 7, speakers were Drs Benjamin W Patrick, on embolism, with a discussion of the possibility of prevention, and James B Rucker Jr, on pathology of embolism and thrombosis. Dr Albert Graeme Mitchell, Cincinnati will give a graduate course in practical pediatrics, March 25-27, at the academy building.

Faculty Changes at Cincinnati University—Dr Carey P McCord, associate professor of preventive medicine at the University of Cincinnati School of Medicine since 1920, has resigned, according to the *Journal of Medicine*. At the January meeting of the board of directors the 'William D Porter Professorship in Obstetrics' was created, in memory of the late Dr Porter, for many years professor of clinical obstetrics. Dr Henry L Woodward, for many years associated with Dr Porter as professor of obstetrics, was appointed to the new professorship. Dr Porter died Sept 27, 1935.

Public Health Lectures in Cincinnati—The Academy of Medicine of Cincinnati and the University of Cincinnati College of Medicine are sponsoring a series of public health addresses for the public Sunday afternoons. Dr William Muhlberg, medical director Union Central Life Insurance Company gave the first February 23, on "Preventive Medicine. Following are the rest of the series:

Dr Alfred Friedlander dean of the college of medicine Your Heart Its Care in Health and Disease March 29
Dr Richard S Austin professor of pathology Cancer April 26
Dr Emeron A North professor of psychiatry Mental Health May 29

OREGON

Society News—Dr Frank R Menne, Portland, addressed a joint meeting of the Multnomah County Medical Society with the University of Oregon Medical School Seminar, January 22 on "Recent Advances in the Study of the Cause of Cancer."—Dr Matthew C Riddle, Portland, addressed the Lane County Medical Society, Eugene, December 20, on "The Anemias Their Diagnosis and Treatment."

Graduate Course in Ophthalmology and Otolaryngology—The Oregon Academy of Ophthalmology and Otolaryngology and the University of Oregon Medical School will sponsor a week of intensive work in those subjects March 30-April 4 at the medical school. Drs John E Weeks and Frank R Menne Portland will supervise a course in ocular pathology and Olof Larsell Ph.D., a course in dissection of the head and neck. Lectures and clinics will be given by Drs Harry S Gradle Chicago William L Benedict Rochester, Minn William P Wherry, Omaha and Dean M Lierle Iowa City. Information may be obtained from Dr Augustus B Dykman Medical Dental Building Portland.

PENNSYLVANIA

Society News—Dr Arthur G Davis, Erie addressed the Erie County Medical Society, January 8 on "Progress in Treatment of Fractures of the Spine."—A symposium on socialization of medicine made up the program of the Lycoming County Medical Society, February 14, at Williamsport. Speakers were Drs John P Harley, Williamsport, on hospital insurance plans, La Rue M Hoffman, Williamsport, the Epstein bill, Frederic C Lechner Montoursville, compulsory sickness insurance in Germany, and Wilbur E Turner Montgomery, compulsory sickness insurance in England.—Dr Damon B Pfeiffer, Philadelphia addressed the Montgomery County Medical Society, Norristown, February 5, on "Surgical Diseases of the Colon and Rectum."—Dr B B Vincent Lyon, Philadelphia addressed the Lehigh County Medical Society, Allentown, February 11, on "Diagnosis and Medical Management of Cholecystitis."—Dr Ralph M Tyson, Philadelphia discussed "Problems in Infant Feeding" before the Cambria County Medical Society, Johnstown, February 13.

Philadelphia

Symposium on Diabetes—The meeting of the Philadelphia County Medical Society, February 26, was devoted to a symposium on diabetes with the following speakers: Drs Elliott P Joslin Boston Trauma in Relation to Diabetes, Russell Richardson, Immunity in Diabetes, and Cyril N H Long, Pituitary, Adrenal and Pancreatic Diabetes. Dr Long presented a motion picture on "The Effects of Hypophysectomy and Adrenalectomy upon Pancreatic Diabetes."

Committee to Investigate Mental Hospital—The mayor of Philadelphia has appointed a committee of physicians to investigate conditions at the Philadelphia Hospital for Mental Diseases and make recommendations for improvement. Dr Wilmer Krusen is chairman and members are Drs Frederic H. Leavitt, George C. Yeager, Malachi W. Sloan, Alfred Stengel, Frederick H. Allen, Paul J. Pontius, Edward A. Steinhilber, Ruth H. Weaver and Dorothy C. Blechschmidt.

University News—The residuary estate of the late Dr Delno A. Kercher, amounting to about \$116,000, was awarded to the University of Pennsylvania School of Medicine, January 29. The will specified that the bequest was to be used for a loan fund for students in the medical school after their first year, graduate students and research workers. Dr Walter Bradford Cannon, George Higginson professor of physiology, Harvard Medical School, Boston, delivered the Alpha Omega Alpha Lecture at Jefferson Medical College, February 14. Dr Cannon's address was entitled "Serendipity." The William Potter Memorial Lecture was delivered at the college, February 7, by Dr Dean Lewis on "Epochs in the Development of Surgery."

VIRGINIA

Health at Richmond—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended February 15, indicate that the highest mortality rate (24.1) appears for Richmond and the rate for the group of cities as a whole, 13.9. The mortality rate for Richmond for the corresponding week of 1935 was 18.2 and for the group of cities 12.6. The annual rate for the eighty-six cities for the seven weeks of 1936 was 13.4, as against a rate of 13.1 for the corresponding period of last year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Society News—The Northampton County Medical Society was addressed, January 3, by Drs James Morrison Hutcheson and Beverley R. Tucker, Richmond, on "The Rationale of the Application of Certain Surgical Measures to the Relief of Hypertension" and "Neurological Aspects of Pellagra," respectively. At a meeting of the Patrick-Henry Medical Society in January in Bassett's, Dr John E. Gardner, Roanoke, spoke on diseases of the chest. Dr Frederick M. Hodges, Richmond, discussed "Roentgen Therapy" before the Lynchburg Academy of Medicine, January 6. At a meeting of the Roanoke Academy of Medicine, January 6, speakers were Drs Charles A. Young, "Interpretation of Changes in the Eye Grounds," John E. Gardner, "Normal and Pathological Considerations," and Harry Golston, "Clinical Significance of Auricular Fibrillation with Electrocardiograms."

WASHINGTON

Medical Museum—A collection of antiquated surgical instruments, assembled by the Puget Sound Surgical Society, will serve as the nucleus for a medical museum in Seattle, the *Bulletin* of the King County Medical Society announces. Dr Karl H. Van Norman, superintendent of the King County Hospital, Seattle, has assigned space on the twelfth floor of the institution for the collection, and Dr Joel W. Baker will supervise it. Contributions for the museum, which is being sponsored by the surgical society, are being solicited.

Society News—Drs Frederick R. Fischer and Otto M. Rott, Spokane, addressed the Yakima County Medical Society, Yakima, January 12, on "Mesenteric Adenitis in Children" and "Methods of Procedure in Diagnosis of Intracranial Complications of Ear Diseases," respectively. Dr Ralph A. Fenton, Portland, Ore., addressed the Walla Walla Valley Medical Society, Walla Walla, January 9, on "Nose, Ear and Throat Conditions from the General Practitioner's Viewpoint." Dr William W. Mattson, Tacoma, addressed the Pierce County Medical Society in Tacoma, January 14, on "The Evolution of Blood Transfusion."

WISCONSIN

Society News—At a meeting of the Eau Claire County Medical Society, Eau Claire, January 27, speakers were Drs Joseph W. Gale, Madison, on "Surgical Treatment of Pulmonary Tuberculosis," Arthur G. Sullivan, Madison, "Medico-legal Medicine," and Roy E. Mitchell, Eau Claire, "Ten Minutes of Medical News." Dr William J. Bleckwenn, Madison, addressed the Fond du Lac County Medical Society, Fond du Lac, January 25, on "Brain Injuries: Their Diagnosis

and Treatment'—Dr Louis A. Buie, Rochester, Minn., addressed a joint meeting of the Kenosha and Racine County medical societies, January 16, on "Proctology for the General Practitioner, the Internist and the Surgeon." Drs Carl S. Williamson, Green Bay, and Matthew A. McGarty, La Crosse, among others, addressed the Milwaukee Society of Clinical Surgery, January 28, on "Subphrenic Abscess as a Complication of Biliary Tract Infection and Surgical Intervention" and "Rationale of the Injection Treatment of Hernia," respectively. Dr Louis A. Fuerstenau, Milwaukee, was elected president and Dr William J. Carson, Milwaukee, secretary.

GENERAL

Medical Bills in Congress—Bill introduced H. R. 11171 introduced by Representative Kramer, California, proposes to authorize an appropriation of such sum as may be necessary to provide for the enlargement of the Veterans Administration hospital at San Fernando, Calif.

Microscope Stolen—The North End Clinic, Detroit, announces that a Leitz-Wetzlar microscope was stolen from the clinic's laboratory, January 27 or 28. The microscope number is 302173, with oil objective number 150362. It has a high dry and low power lens mounted in the triple nose piece, ocular $\times 10$, Abbe condenser, no substage mirror and bears a detachable uncalibrated mechanical stage. It is reported that a gang in Detroit has been stealing microscopes and shipping them to distant points for disposal. Any information on this instrument should be communicated to Mrs. Eleanor J. Ford at 936 Holbrook Avenue, Detroit, director of the clinic.

States Act to Control Water Pollution—New York and New Jersey entered into a compact, January 24, to control pollution of water in the metropolitan area of New York. This action is the outgrowth of the work of a Tri-State Treaty Commission appointed by the legislatures of New York, New Jersey and Connecticut in 1931. The compact was drawn up and presented for action by the legislatures in 1932. It was enacted into law in New York in that year to become effective when ratified by New Jersey; the latter state passed its enabling law in 1935. The compact will become effective with respect to Connecticut as soon as that state enacts similar legislation. Briefly stated, the aims of the compact are to eliminate offensive pollution, to make beaches safe for swimming and recreational purposes, and to return certain areas now condemned to shellfish culture. The pact was approved by Congress in August 1935.

Meeting of Tuberculosis Association—The thirty-second annual meeting of the National Tuberculosis Association will be held at the Municipal Auditorium in New Orleans, April 22-25. The preliminary announcement mentions the presentation of papers by authorities and, in addition, a symposium on tuberculosis among different peoples, covering Negroes in the United States and racial aspects of tuberculosis in Mexico and Puerto Rico, with the following physicians as speakers: Esmond R. Long, Philadelphia; Donato Alarcon, Mexico City; Jose Rodriguez Pastor, San Juan, P. R.; and Paul P. McCum, Sanatorium, N. C. Dr Alarcon will also deliver an address at the opening general session, Wednesday evening, entitled "The Campaign Against Tuberculosis in Mexico." The National Conference of Tuberculosis Secretaries will meet at the Roosevelt Hotel, Wednesday, April 22, with Dr Kendall Emerson as the speaker on "Recruiting and Training Tuberculosis Workers." The administration and function of tuberculosis associations will be the theme of a symposium at this meeting.

Society News—Dr Richard Kovacs, 1100 Park Avenue, New York, is executive of the American committee for the International Congress on Physical Medicine, which will be held in London, May 12-16. American participants will sail from New York on the *Britannic* and return May 31 on the *Pennsylvania*. Dr John A. C. Colston, Baltimore, was elected president of the Mid-Atlantic branch of the American Urological Association at the second annual meeting in Washington, D. C., January 23. The American Physiotherapy Association, an organization of physical therapy technicians, will hold its annual meeting at the Hotel Ambassador, Los Angeles, June 28-July 2. The second Congress of the Pan-Pacific Surgical Association will be held in Honolulu, T. H., August 6-14. The American Physical Education Association will hold its annual meeting in St. Louis, April 15-18. At a meeting of the midwestern section of the American Congress of Physical Therapy in Rochester, Minn., March 4-5, speakers will include Dr Melvin S. Henderson, Rochester, on "Physical Therapy in Relation to Orthopedics," Dr John S. Coulter and Howard A. Carter, B.S., secretary, Council on Physical

Therapy, American Medical Association, Chicago, "Studies in Tissue Heating with Short Wave Diathermy" and Dr. Disraeli W. Kobak, Chicago, "Influence of Short Wave Diathermy on the Blood." A symposium on arthritis will be presented by Drs. Ralph K. Ghormley, Philip S. Hensch, Charles H. Slocomb and Frank H. Krusen, all of Rochester.—The National Society for the Advancement of Gastro-Enterology will hold its annual meeting in Atlantic City, June 5, with headquarters at Haddon Hall.—The National Congress of Parents and Teachers will hold its annual convention in Milwaukee May 11-15.

Government Services

Meat Inspection Chief Dies

Adolph J. Pistor, D.V.S., chief of the meat inspection division of the Bureau of Animal Industry, U.S. Department of Agriculture, died in Washington January 25, aged 59. Dr. Pistor entered the service of the bureau in 1898. He took an active part in the organization of the meat inspection service after the passage of the federal law in 1906 and later was assigned to administrative duties in Washington. He became chief of the service Jan. 1, 1935.

Tribute to Dr. Cumming

In a discussion of the Treasury and Postoffice Appropriation Bill, 1937, on the floor of Congress, February 5, Mr. John J. Boylan, congressman from New York, gave a brief outline of the career of Dr. Hugh S. Cumming, recently retired surgeon general of the U.S. Public Health Service. Mr. Boylan said:

I venture to express the opinion that many members of this house regret the retirement of the surgeon general from active duty. Many of us should take this opportunity to express gratitude for the excellent work which he has performed for this nation. I am sure that he will have that happiness and contentment which comes to every man whose services have been honestly and faithfully performed.

Twenty-One States Share First Social Security Grants

United States Treasury checks representing the first social security grants to states for assistance in their aid to the aged, the blind and to dependent children, were in the mails February 13. Among the first checks sent were:

To Arizona	\$ 4,725 00
To Connecticut	2,520 00
To District of Columbia	9,450 00
To Idaho	6,300 00
To Maine	26,250 00
To Mississippi	8,820 00
To Nebraska	15,540 00
To New Hampshire	5,040 00
To North Carolina	3,324 99
To Wisconsin	52,149 99
To Wyoming	4,161 40

In states the public assistance plans of which are approved by the Social Security Board, the federal government will match state funds dollar for dollar in the case of aid to the needy aged and the blind, and one dollar for each two dollars disbursed by the states for aid to dependent children. An additional 5 per cent of the federal grants to states for old age assistance and aid to the blind will be paid to the states to share the cost of the administration of these two forms of public assistance.

The twelve states with approved plans for aid to the blind are:

Arizona	Maine	North Carolina
Connecticut	Mississippi	Pennsylvania
District of Columbia	Nebraska	Wisconsin
Idaho	New Hampshire	Wyoming

In addition to the states which have had one or more public assistance plans approved, a number of other states have submitted their public assistance plans for approval by the board, and still other states are expected to do so shortly.

To be approved by the Social Security Board, under the terms of the Social Security Act, state public assistance plans must provide for cash payments to needy aged persons, to dependent children living in their own homes or the homes of relatives, and to the needy blind, in all parts of the state. A single state agency must administer the plan or supervise its administration if the plan is directly administered by the counties. This state agency must grant the opportunity for an appeal from any decision of a county denying assistance to an applicant.

Report of Cancer Research Fund

In the annual report of the Imperial Cancer Research Fund the retirement of the director, Dr. J. A. Murray, who had occupied his post since 1915, the second year of the inception of the fund, is recorded. With Dr. Bashford he laid the foundation for the experimental investigation of cancer by proving that it is not confined to man, as was at one time believed. The material they collected on the natural incidence of cancer in mice provided investigators with a knowledge of the disease in this species equal to that in man. It enabled Dr. Murray subsequently to demonstrate the hereditary factor of the disease. He confirmed the observations of Jensen on transplantation and showed the important fact that this was due to an actual transplantation of living cells and not to an infection of the new host by some agent separable from the cells. The subsequent discovery by Peyton Rous of tumors of the fowl which can be transmitted without the intervention of living cells led to numerous reinvestigations of Dr. Murray's early work, which have served to confirm it. Of equal importance are his investigations of the phenomena of immunity which renders a normal animal resistant against transmission of the disease by transplantation.

The new director is Dr. W. E. Gye, whose work on the pathology of cancer is well known. In his report he points out that the facts that in all vertebrates normal cells can undergo malignant transformation and that such cells possess everywhere the same fundamental properties are the foundation of the experimental investigation of cancer. Of the diseases that can be produced experimentally, few if any simulate the normal human disease so closely as cancer.

CANCER NOT INCREASING AT AN ALARMING RATE

Dr. Gye points out that the prevalent opinion of a rapid increase of cancer was based on the crude figure of total cancer mortality. Bashford analyzed cancer mortality with reference to the different organs, separating accessible sites, where the diagnosis was easy, from inaccessible sites, where the diagnosis was difficult. He found that the recorded increase fell largely, though not entirely on inaccessible sites, especially the stomach, while the skin and uterus showed no increase. Investigation of more than 10,000 cases at the London hospitals showed in the accessible sites that only 9 per cent were not recognized clinically, while the figure for inaccessible sites was 38 per cent—an astonishingly high figure for large hospitals with the most advantageous conditions for diagnosis. Thus the recorded total mortality of cancer must be much lower than the actual mortality. The greater attention paid in recent times to the clinical recognition would tend to diminish the extent of missed diagnoses and increase the recorded mortality.

EXPERIMENTAL CANCER INVESTIGATIONS

Transplantation of cancer was found to be successful only within the species from which the tumor was derived. Hence the failure to transmit human cancer to the lower animals. The propagation of a mouse cancer in mice can be carried on indefinitely. It follows that the *primum movens* of the disease is in the cancer cell itself and successive generations of normal mice are unable to affect the malignant properties of the transplanted cells. There is an important practical deduction. The laboratories of the Imperial Cancer Research Fund are willing to investigate so-called cancer cures. But almost all the "cures" brought for examination are based on an assumption that cancers arise and grow because of some constitutional defect in the body of the patient. It has been assumed that they pro-

gress because some gland is inadequate in what is supposed to be its function of controlling growth. These "cures" have all been tested, and they have been found useless.

VIRUS CANCERS

In 1911 Peyton Rous described a spindle cell sarcoma of the domestic fowl that could be propagated not only by grafts but by cell-free filtrates. Subsequently a score or more of filtrable avian tumors of diverse structure were described. Thus there exists a group of tumors produced by intracellular agents indistinguishable from the viruses. Dr Gye therefore assigns to these agents a specific part in the genesis of tumors. The recent discovery by Shope of a filtrable papilloma of the cottontail rabbit has broken the apparently absolute difference in respect of filtrability between tumors of mammals and tumors of birds. Another important discovery was made by Professor McIntosh at the Middlesex Hospital. Tumors were started in fowls by injecting tar subcutaneously, and these were transplanted into normal fowls. In some cases it was found possible, once the difficulties of propagation had been overcome, to transmit the growths by means of cell-free filtrates. The part played by tar in cancer causation is thus different in kind from the part played by the filtrable agent, which can be obtained again and again from successive generations of the tumor.

Changes in the English Population

The Registrar-General's Statistical Review of England and Wales for 1933 has just been published. The estimated population in the middle of the year was 40,350,000, consisting of 19,357,000 males and 20,993,000 females. The total is 0.37 per cent greater than the estimated population for the previous year. The average age of the population is gradually increasing. In 1933 the figure for males was 32.2 years and for females 33.9. In 1931 the figures were respectively 31.8 and 33.5, in 1921 they were 29.9 and 31.2.

THE FALLING BIRTH RATE AND THE APPROACHING FALL OF POPULATION

The continuous fall in the English birth rate during the last half century is of first importance. As during all this period there has been an annual increase of population, the inevitable decline may seem paradoxical but is easily explained. It is a result of the fact that the recent birth rates are not sufficient to replace the younger persons of future generations while the more remote birth rates, which are greater, are sufficient to more than replace the older persons. Moreover the diminished death rate of recent years further maintains the older members of the population. The result is, as the figures show, a constantly aging population. The older persons, who represent former birth rates, can for a time conceal by their numbers, the serious fall of the younger. But it is on the younger members, more specifically on the number of women of the reproductive age that future population depends. These women have been reproduced for some years in sufficient number to replace those passing out of the reproductive period. If all other conditions remain exactly the same the result must be in time that the persons of every age are not replaced, which means that the whole population must fall irrespective of any further fall in the birth rate. But this is also going on. Hence the registrar general states that the reduction of the population is 'likely to come earlier than a few years ago was considered probable.'

The live births in 1933 were 580,413 or 33,559 fewer than in 1932. The birth rate was 1.44 per thousand of population, the lowest on record. Only two other countries, Austria and Sweden had lower birth rates. The rate of increase of the population was 2.1 per thousand the lowest on record. The magnitude of the fall of the birth rate is shown by the comparison with the birth rate in 1876 which was 36.3. Thus a fall of 60 per cent has taken place in the last fifty years.

Maternal Mortality

The Fellowship of Medicine arranged a debate on the motion 'That the Present Rate of Maternal Mortality Is a Discredit to Modern Obstetrics.' Leading obstetricians took part. Prof J. M. Munro Kerr said that the mortality was in no way mysterious and was due to the fact that the means at hand was not employed to prevent it. The mortality at two maternity hospitals in London, with institutional and domiciliary services, was as low as 0.7 and 1 per thousand, which was five or six times lower than the general rate for England and Wales. The death rate from eclampsia was the criterion for assessing the quality of antepartum care. In the country generally there was no evidence of lowering of this rate, while in the services mentioned death from eclampsia rarely occurred. The only solution in densely populated areas was that the family physician should give up maternity work and leave it to municipal midwives and specialists.

Prof G. I. Strachan said that since 1906 the maternal mortality had risen from 3.74 to 4.6 per thousand births. But the Netherlands was the only country of any account that could show a lower mortality than England and Wales. He gave high American figures: 10 per thousand for the state of Georgia in 1931 and 8.1 for Louisiana in 1934. He considered that the increasing incidence of abortions, the majority of which were procured, was one of the most important causes of maternal mortality. Another was the decrease in the size of the family, which meant a higher proportion of primiparas. He deprecated unnecessary intervention in labor but thought that there was no easy road to success in improving the mortality.

Professor Dougal said that the figure for maternal mortality in 1933 was 4.32 per thousand, which would be reduced to 3.7 if an estimated number of abortions were added—not an alarming mortality but higher than it should be, because many deaths could have been avoided if certain conditions were fulfilled. He considered that overcrowding of the towns was, as in the United States, responsible for our high mortality. The conduct of labor should be left to the midwife, but the general practitioner was the proper person to supervise the health of the pregnant woman and to detect abnormalities. In labor he should be available for the diagnosis of abnormalities and the treatment of those with which he was competent to deal or must deal because of urgency. For others the obstetrician should be available.

Dr Bethel Solomons, formerly master of the Rotunda Hospital, Dublin, found the present system of obstetric teaching unsatisfactory. The student was required to attend a certain number of labors, but he should be required to attend them all through and not simply at the end. No one should be allowed to practice until he had done graduate work under supervision. As long as the number of forceps interventions remained high, with the proportion of mangled and dead women and children, it could not be said that the present state of obstetrics was creditable.

Second British Red Cross Unit for Abyssinia

The response to a broadcast appeal for funds to allow further help to be sent to the Abyssinians by the British Red Cross Society has been so prompt that the dispatch of a second unit was soon announced. Another appeal for \$15,000 to enable an airplane to be presented to the Ethiopian Red Cross was also successful, sums varying from \$2.50 to 25 cents from a little box, being received.

The Australian Red Cross has asked the International Red Cross at Geneva if another ambulance outfit is needed. If so, it will consider the practicability of sending a complete unit with four physicians and ten orderlies, to be maintained by public subscription. Australia is also prepared to send funds and Red Cross equipment to Italians, if needed.

The Pathologist and the Surgeon in Preoperative Diagnosis

By a recent decree, the government changed the name of the Societe de chirurgie to Academie de chirurgie. Now with two medical academies in France, the former members of the Societe de chirurgie probably will be allowed to wear the historic green embroidered dress coat, the pride of the academician. The Societe de chirurgie, only 92 years old was in fact the heir of the ancient Academie royale de chirurgie and it is satisfying to see this famous name restored.

At the session of Dec 11, 1935, Drs. H. Welti and Rene Huguennin pointed out the advantages of preoperative diagnosis in surgery of malignant tumors. Preoperative diagnosis is an investigation similar to biopsy, made before the operation but it is a "directed biopsy." Instead of taking off a bit of a tumor at random the surgeon, guided by experience, can choose the significant parts of the pathologic tissues and have them examined at once. He can be informed of the extent of the secondary lymphatic invasion. He can, in short, benefit by every bit of information secured during the operation. On the other hand, if the clinical diagnosis was wrong the extemporaneous examination of the removed parts corrects it. This is of great importance in some cases. For instance, in a case of careful diagnosis of cancer of the thyroid reported by Drs. Welti and Huguennin, ablation of the organ was averted by the report of the pathologist working in collaboration with the surgeon. His conclusions showed a simple although long-continued thyroiditis with hyperplasia. The same thing may happen in cancer of the breasts. "directed biopsy" gives an almost perfect assurance of the benign or malignant character of the tumor.

The technic of the immediate examination differs according to the organs examined. On the whole the constant collaboration of the surgeon and the pathologist in the course of the operation demands both great training and the spirit of cooperation. But, in the future, those details will be perfected and the pathologist will have his place as a matter of routine, under every thoroughly equipped surgeon.

Conference on Preventive Pediatrics

The fifth conference of the International Association for Preventive Pediatrics met in Basel, Switzerland, last September. The first topic for discussion was the arrangements to be made for keeping infectious diseases away from children's hospitals. Many opinions were expressed. They were, generally speaking, divided between the idealistic view of those who suggested perfect but often too complicated devices, and the practical views, which emphasized the difficulty of getting rid of the old type hospitals conceived on former standards and difficult as a rule to manage with modern ideas. Dr. Husler of Munich pointed out that a good location of the hospital, good air and light and an exacting technic by doctors and nurses are of great importance. Dr. Lust of Brussels is a partisan of maximum attention to detail. He thinks that the dispensaries must be absolutely separated from the wards. He is suspicious of visiting relatives and friends, whom he asks to wear blouses and masks when visiting the children. Dr. R. Debre of Paris proposes that an assistant be charged with investigation of the homes of sick children to discover infectious cases and order the necessary preventive measures before the admission of the child to the hospital. Dr. Bela Schick of New York stated that the problem is much more difficult to solve in hospitals devoted to chronic diseases than in ordinary ones. For the prevention of diphtheria it is better to practice as a routine toxoid-antitoxin immunization in

grown children or the use of antitoxin in babies. If weakly undernourished children can be treated at home, it is better not to admit them to the wards. The principal contaminations come from the environment—children, parents or hospital staff.

The conference adopted the following conclusions:

It is absolutely necessary to fight against contagious disease in hospitals by organization of proper conditions and exact supervision of the staff, the children and the things they use and touch. Management of admissions and medical care also must be exact including especially an investigation at the homes of sick children. The nurses must be specialized and as far as possible, not changed too often. Every member of the staff must be carefully examined periodically. As for the babies, the wearing of a mask is recommended, as well as limitation of visits, and the isolation of the children in the waiting rooms. Overcrowding of wards and shortage of staff are calamitous.

Another subject, reported by Dr. Genevieve of Paris, was pulmonary tuberculosis in the school. He said that tuberculosis affects one in a hundred of the schoolboys or girls. The diagnosis requires a roentgen examination and consequently must be made in the dispensaries. The infection generally originates not with children but through teachers or school employees who must be subject to periodic medical examinations. To these individual measures must be added every possible sanitary improvement of the school itself and of individual hygiene. Superinfections too often come from the family. The points emphasized were the role of the school staff in infections, masked bacillus carriers, use in the school of the cutaneous reaction test, supervision of the child outside the school, routine examination of the school staff, usefulness of the pupil's card (book), the development of open-air classes and playgrounds, the limitation of working hours and the supervision of the diet of children.

Treatment of Detachment of Retina

After many experiments Gonin in Lausanne six years ago, made known his new method for treatment of ablatio retinae. Although much of his operative technic has been superseded by newer procedures Gonin must be accredited with the discovery of the fact that in cases of retinal detachment a laceration is always present. Professor Lohlein spoke on this subject before the Berlin Medical Society. Ablatio occurs chiefly in myopic eyes but also in those showing senile or traumatic forms. In the first four decades of life, ablatio is much rarer than in the later years. Of forty-five cases of Lohlein's own observation, eleven patients were from 10 to 40 years of age and thirty-two from 50 to 80. If one agrees with Gonin that retinal laceration is responsible in a majority of cases so must one consider as a second cause a partial liquefaction of the vitreous humor. During the war numerous cases of traumatic retinal lacerations were observed. It is frequently difficult to determine the exact location of the laceration. Usually it lies in the periphery of the superior temporal region. There appears to be a connection between the condition of myopia as well as of senile eyes and this location which leads toward degeneration.

Gonin's procedure consists in determining the location, opening the sclera and pricking with Paquelin's cautery in the region of the laceration in order that a scab may be formed. As the exact location of the laceration is frequently difficult to determine the cautery needle may produce injuries and cicatrization may follow the scratching. Because of the crudity of the Paquelin method, other procedures have been sought that are based on the principle of determining an adhesive inflammation. Next to cauterization with alkali the most important procedure today is diathermic coagulation. Lohlein worked endlessly,

using procaine hydrochloride anesthesia, which obviated the hindrance of winking. The region of the laceration proper was "parahmentized" by a flat electrode, round about this area several perforations were made with a sharper electrode. The after-treatment is vital to success. During the first week the patient's head, completely bandaged and light tight, is not moved, then a first change of dressing takes place. Throughout the second week as well a state of quiet is maintained. During the third and fourth weeks the wearing of glasses that admit light through a narrow aperture facilitates complete cure. Professional care should be exercised for three months after the operation. Lohlein followed this procedure in forty-five cases. Of these, 42 per cent resulted in recovery. 24 per cent were improved and 34 per cent showed no improvement. Successful outcome of course is dependent on the special conditions of each separate case. In elderly persons, because of the weakness of the tissue, operation should not be attempted. Too great a loss of the vitreous humor during the operation or secondary hemorrhages often cause failure.

In regard to the prophylaxis of this condition, it would perhaps be possible to accomplish something in the course of the marriage consultation of hereditarily predisposed persons. Care should be exercised moreover in severe myopia because of the danger of traumas (the most frequent cause of detachment) from sports, especially from ball playing. Finally, it is advisable that patients with contusion of the eyeball remain in bed until, with the stopping of hemorrhage, examination may be undertaken.

The Crisis in Research on Twins

The racial political stand of the German government has as its foundation a firm belief in the importance of hereditary as opposed to environmental influences. Results of research on twins have been taken as substantiating a preponderance of hereditary predispositions. The whole structure of this theory, however, has been severely shaken by the publication in the *Wiener klinische Wochenschrift* (48 868 [June 28] 1935) of an article by Professor Alfred Greil of Innsbruck which he calls "The Crisis in Pathologic Development of Twins. Etiology of Mongolian Idiocy." This article contains a plea for an entire reorientation in the field of research on twins. Not enough attention, he says, has heretofore been paid to certain essential facts of prenatal development. For him uniovular twins are a fortuitous occurrence, a minus variation due to a checking of the formation of the uniform amniotic cavity. In these separated sections the inequality of the sacs or inlets brings about a uniovular twin formation which may manifest itself in any of an uninterrupted teratogenic series of variations in deformed twins, ranging from gemini inaequales, through epistru and epignathu to teratomatous conditions of the sacral tumor, fetal inclusion or tubulodermoid types. If the amniotic sections are fairly equal, normal uniovular multifetation (from twins to quadruplets) originates. These plural fetuses have always in common the chorion, vitelline sac and placenta but separate amniotic cavities that may merge into one although not necessarily.

When this explanation is accepted it follows that uniovular twins and quadruplets do not originate from the accidental splitting of the ovum itself into two or four cells. Twin formation is not fission. Accordingly uniovular twins resemble in no way linked bodies of a single fetus. Pathologic asymmetry in the single fetus as well as in uniovular twins is not determined by the nuclear genotype. All discordances develop epigenetically (that is to say influenced by environment) from absolutely homogeneous and genotypical cell material. These prenatal environmental influences are of much greater significance than the postnatal which result from training and orientation in life.

Since there are no dichorionic uniovular twins, there is added to the problem of their environmental discordance the concordance of binovular twins.

All that which influences the mother during pregnancy may influence the prenatal milieu and in addition reflect hereditary tendencies the significance of which accordingly is greatly reduced. Among prenatal environmental factors may be mentioned an uneven distribution of blood through the umbilical vein as well as pregnancy toxins, exacerbated month by month and leading to cellular and histologic corresponding changes.

This new conception cannot if accepted fail to influence racial-hygienic and even racial political ideology. Moreover it permits one to glimpse in the far off future the possibility of therapeutic or formative intervention in intra-uterine processes.

Mixed Marriages in Germany

In the *Reichsgesundheitsblatt* official organ of the state ministry of health, Dr. (of Philosophy) Gollner in dealing with so-called mixed marriages between Christians and Jews presents certain data on racial relationship which are not to be found as yet in the records of the marriage registries. During the World War these mixed marriages exceeded in number the marriages between Jews. Thus in 1915 to every 100 Jewish marriages there were 105 mixed marriages throughout Germany, and for Berlin the rate was 115 mixed to 100 Jewish. The fruit of these mixed marriages was 0.8 living birth against 2.7 living births among the purely Jewish. The surprising thing is that among the mixed marriages the proportionate number of males born is considerably greater than among the population as a whole. The average birth rate is 107 males to 100 females. In mixed marriages the number of males is 115. In those mixed unions in which the father was Jewish the males born number 119 when the mother was Jewish, 109.

Eggs as a Source of Food Poisoning

In the last year the German press has frequently carried reports of serious and even fatal illness resulting from the eating of duck eggs. Professor Dr. Beller of Ankara published in the *Reichsgesundheitsblatt* the results of an investigation of these cases undertaken by the ministry of health. The cases studied all presented dysenteric symptoms such as are caused by the *Bacillus enteritidis* of Gartner or *Bacterium breslaviense*. This seemed at first readily explicable as due to the penetration of excrement through the egg shells, the habits of ducks being little more cleanly in this regard than those of chickens. However, although dysenteric diseases are frequently encountered in ducks and geese, it was found that in the cases investigated the causative agents could not have been communicated through the egg shells. An examination of 1500 eggs showed positive cultures to be present in seven yolks. Doubtless it was here a question of infection acting through the blood stream. Hen's eggs appear to be less dangerous for in chickens dysenteric disease may be caused by *Bacterium gallinarum* which is not pathogenic in man. Infection from the partaking of hen's eggs is due chiefly to the bacillus of chicken tuberculosis which is closely allied to the causative agent of tuberculosis in man. As it seldom leads to serious acute illness raw hen's eggs emptied out of the shell are relatively harmless. Duck eggs on the contrary, are as a rule only to be eaten after thorough cooking, never while in a raw or underdone condition as is the case, for example when they are served with mayonnaise dressing. It is interesting that peasant folk refrain from eating duck eggs, apparently having learned from general experience the occasionally dangerous character of the eggs. It would seem on the face of it entirely possible by improved hygienic care of chickens and ducks to eradicate such of their diseases as through their eggs constitute a menace to man.

Experiments with Poliomyelitis

The director of a provincial hospital, Dr Kibler of Hall in Wurttemberg, has made a report on the recent poliomyelitis epidemic in southern Germany. Eighty-six cases were admitted to the hospital within three months. Diarrhea was present in only twelve patients. In all, seventeen patients had paralysis. Nine of these complained of stiff neck, a symptom present in thirty-four of those admitted to the hospital. Excessive perspiration was observed in two cases. On the other hand, hypertension and a marked drowsiness as in epidemic encephalitis were frequently encountered. Of nerve reflexes, Babinski's and Oppenheim's were each twice positive. Paralysis appeared in feverish patients as well as in those free from fever. The lumbar puncture carried out in each case for diagnostic and therapeutic purposes showed sixty-five times a pressure exceeding 150, nineteen times above 300 and twice above 500. The number of cells permitted no conclusion as to the severity of the disease. With regard to protein content, Pandy's reaction was positive in thirty-eight cases. The blood picture had to be abandoned as a criterion, owing to the irregular influences of accompanying disorders. Two patients of the entire group died. Lumbar puncture for the purpose of relieving pressure was therapeutically successful.

The permission of the entire population by the disease was greater in this epidemic than generally would be assumed. Incompletely developed cases somewhat resembling influenza frequently took an ambulant course with no paralysis remaining. A strict quarantine of entire communities appears to be the only way in which to obtain successful results in controlling this disease.

Ten Years' Study of Malaria Therapy

During the period 1925-1935, at the Bucharest Neurologic Clinic, 1,224 patients suffering from neurosyphilis were inoculated with malaria. In all cases subcutaneous injections were replaced by the intravenous method, because the period of incubation is shortened. The latent period averaged six days. Professor Paulian, chief of the clinic, endeavored to obtain at least eight attacks of fever but he thinks it best to have twelve attacks. After the cure by quinine, a chemotherapeutic treatment is commenced and administered for another month. Of 525 cases of dementia paralytica, 418, or 79.61 per cent, showed decided improvement. Among cases of syphilitic meningo-encephalitis, 202, or 90.99 per cent, showed improvement. Of 140 cases of locomotor ataxia, 123, or 87.85 per cent, showed great benefit. Of 101 cases of tabes, seventy-eight, or 77.26 per cent, showed improvement. The mortality among 1,070 patients amounted to sixty-four cases, or 5.98 per cent, a considerable decrease in comparison with the figure obtained at the initial stage of malaria therapy, when it amounted to from 17 to 20 per cent.

The malaria therapy had a favorable action first on the mentality. In the spinal fluid the leukocytosis decreased first and then the albumin and globulin content. Finally the blood report improved. No improvement in the serologic manifestations may be regarded as a bad sign and it renders necessary a repetition of the malaria therapy.

The Increase in the Price of Drugs

The law restricting imports has led to a scarcity of foreign made drugs. This is disastrous, as there are no high grade chemicals produced here. Some manufacturers tried off hand to establish factories but their products are inferior in quality. The restriction on imports gave rise to the development of a new industry that of drug smuggling but of course in this way only a small fraction of the demand can be supplied at

fancy prices. The lack of foreign drugs resulted in a rise in prices of the staple medicines. A kilogram of aminopyrine cost wholesale in 1934 13,000 lei, while in 1935 it cost 18,000 lei, at retail it rose from 15,000 to 21,000 lei. The price of foreign quinine in September 1934 was 5,000 lei and at present it is 7,000 lei. The price of arsphenamine preparations jumped up by 33 per cent. English, French and American drugs and proprietary medicines cannot be obtained at all, because, by the law restricting imports, goods can be imported only on a compensation basis, that is, for goods exported. Germany, which is an extensive buyer of Rumanian wheat, maize, cereals, apples and wine, exports the largest quantity of drugs to Rumania. In the first quarter of 1935 Germany exported into Rumania 73,900 Kg of drugs of a value of 41 million lei.

The worst of this situation is that also the home factories raised the prices of their pharmaceutical products. Following the intervention of the Rumanian Medical Association, the ministry of industry is going to take measures against the price policy of the home factories. The ministry has demanded enlightenment on the cost of raw materials, the cost of production, and the sale price. Then the ministry of public hygiene will fix the sale price of home made medicines.

Providing the Rural Districts with Physicians

M. Titu Gane, state secretary of the ministry of public health, seeing the immense difference between the public health in cities and in villages, took a strong stand to improve the situation in the villages. In several places first aid stations and examining centers have been established, where the rural population is accorded free medical consultation and laboratory tests. To this end the government has appropriated more than 14 million lei in the last two years. With this will follow an increase in the number of village doctors. The government will make an agreement with doctors who are willing to locate in villages whereby they will be paid a monthly salary of 2,500 lei (\$25), for which they are obligated to reside in the designated village and to hold consultations four hours daily. The government will create new districts, so that no physician shall have under his care more than five or six villages. The minister will see that every district is only as large as to allow the physician to visit the remotest village of his district within one day, by carriage. The roads are not fit for motor traffic.

For the campaign against tuberculosis, the national league has more than 86 million lei, from which sum 36 million has been collected from private contributions. This large sum will be devoted to the building of sanatoriums which are badly needed.

It is hoped that this action of the ministry of public health will decrease the congestion of physicians in cities and will provide at least 1,500 physicians with a living.

Centenary of the Birth of Professor Kalinderu

The centenary of the birth of Professor Kalinderu has been celebrated all over the country, medical societies, almost without exception, having arranged special meetings with memorial addresses. Professor Kalinderu was born in Bucharest in 1835. After completing grammar school in Rumania he went to Paris, where he attended the university and then worked at different clinics, especially at the Salpetriere, where he was engaged at the laboratory of the French neurologist Jean Martin Charcot. Here he wrote a treatise on cranial cephalotripsy. In 1870 he returned to Rumania and was appointed professor at the University of Bucharest, where with Paul Petrucci he established the incidence of leprosy in Rumania and compiled statistics. He showed that the greatest number of cases of leprosy occurred in the Dobrudja and the swampy parts of the Danube regions. He established the familial character of this disease and tried to explore all the foci. He especially dealt with the nervous forms, which were so difficult to diagnose.

At the International Conference on Leprosy in Berlin, Kalinderu achieved great success with his new ideas on diagnosis and treatment. He read a paper on a type of leprosy identified by Prof. Georges Marinesco and described by Morvan. Kalinderu studied in association with Professor Marinesco the disturbances of sensation occurring in leprosy.

Kalinderu worked also in other fields. With Professor Babes, late director of the Bucharest antirabies institute, he investigated the pathogenesis of tuberculosis. He drew the attention of the medical world to the unpleasant consequences of the use of cosmetics containing lead. He was led to this discovery by observing that women in general but demimondaines in particular often complained of intestinal cramps and other symptoms characteristic of plumbism. He found that in many cases lead was introduced into the organism through the use of hair dyes.

During his career, Kalinderu wrote about fifty treatises, many of which were translated into foreign languages.

Dec 31, 1935

The Congress of Orthopedics

At the fourteenth National Congress of Orthopedics recently held in Bologna, the first topic was obstetric trauma and obstetric paralysis of the shoulder. Prof. Giulio Faldini of the University of Parma reviewed the literature, reported some cases and concluded that obstetric trauma and obstetric paralysis of the shoulder occur about once in a thousand cases. Boys are more frequently affected than girls, the right side is more frequently involved than the left one, and bilateral involvement is rare. The most frequent cause of obstetric paralysis is obstetric trauma. Maneuvers on the arm to obtain disengagement of the shoulders are frequently the cause of injuries in the shoulder. Obstetric paralyses are due to interruption of the nerve plexus roots or to truncal lesions. Obstetric trauma of the shoulder is more frequent than obstetric paralysis and can be classified into distortions and fractures of either the clavicle or the scapulohumeral joint. The injury most frequently seen is epiphysiochondral detachment. In new-born infants the roentgen examination may show a fracture of the clavicle. At the age of 5 months the diagnosis can be made and can be confirmed at the age of 1 year when the paralytic syndrome is definitely established. The performance of operations on the plexus is not advisable during the early life of the patient. It is better to resort to early electrotherapeutic and postural treatment and later to perform an operation. The prognosis is favorable.

The second official topic was internal lesions of the knee. Professor Dehla of Venice in collaboration with Dr. Tommasini, presented an illustrated paper of more than 100 pages. Diseases of the menisci are the most important of all internal lesions of the knee. In cases of suspected meniscal rupture it is advisable to wait for the results of conservative treatment, because if partial ruptures take place transversely they may heal spontaneously. In complete meniscal rupture an early operation is advisable to avoid the development of secondary arthritis. A menisectomy and not a suture is the operation indicated. Satisfactory results are obtained in 80 or 90 per cent of the cases. The next congress of orthopedics will take place in Rome and the official topic will be the treatment of open fractures.

Commemorations of Italian Anatomists

Prof. Luigi Castaldi of the University of Cagliari recently organized ceremonies in memory of Filippo Civinini. Filippo Pacini and Atto Fieri which took place in Pistoja, the home town of these anatomists. Civinini, who was a teacher of

pathology and surgical principles in the University of Pisa, left to posterity work on the bones, the structure of the placenta, and the spine, ligament and toramen that are named after him. He wrote a summary on embryology. Pacini is the discoverer of Pacini's corpuscles. Pacini's discovery of the reception of sensations by these ganglions opened the way to the development of esthesiology. Tigris established the behavior of the splenic veins and the existence of splenic endothelial cells and of splenic reticular connective tissue. The anatomic preparations on the reticulo endothelial system made today are no different from those prepared with reticular tissues of the spleen by Tigris in 1849. He also made contributions on tubercle bacilli and the comma bacillus which he isolated from the blood of patients with Asiatic cholera.

A Center for Hydrologic Research

A center of scientific research has been established at Salsomaggiore, near Parma, for studies on thermal springs. The new center is connected with the medical clinics of Milan and Genoa and with the obstetric clinic of Milan, and its purpose is to study the action of the waters of Salsomaggiore in diseases of internal medicine and in gynecologic disorders, their influence on various internal organs, and particularly on the glands of internal secretion. The research institute thus founded will constitute the nucleus of a more complete organization for the hydrologic training of physicians, which is being at present promoted by high Italian scientific authorities, headed by Professor Rondoni, "academician of Italy."

Results of the Government Examinations in Medicine

During the year 1934, 1,677 graduates in medicine took the government examinations for licensure in medicine and surgery. The examinations were successfully passed by 1,522 of that number, while 155 (about 9.35 per cent) failed. The University of Naples furnished the largest number of graduates (311). The largest number of graduates (231) were enrolled also at the University of Naples for their government examinations.

Studies on the Finger Prints

Prof. V. Tirelli of the University of Turin has reported to the Academy of Medicine his research on the hereditary transmissibility of the patterns of the finger prints. It seems that a marked uniformity of types may result from hereditary influences. Professor Tirelli's research leads him to believe that it is possible to apply Mendelian laws to the familial transmissibility of certain composite types of finger prints.

Marriages

MARTIN J. RYAN JR., Harrison, N. Y., to Miss Elizabeth McCawley of New York in Carbondale, Pa. Dec. 28, 1935.

EDGAR L. AABERG, Peoria Heights Ill. to Miss Jean Littlejohn of Springfield in December 1935.

HUBERT A. ROYSTER JR., Philadelphia, to Miss Elizabeth Rutan of Sewickley, Pa. January 17.

LLOYD B. SHEFFIELD, Dallas, Texas, to Miss Katie Pearl Reynolds of Waco Dec. 28, 1935.

FREDERICK H. HOWARD, New York, to Miss Lulu O. Smith of Racine, Wis. Dec. 28, 1935.

ORVAL F. SWINDELL, to Miss Dagmar T. Knudsen both of Boise, Idaho Nov. 23, 1935.

LLOYD A. STAHL, to Miss Dorothy E. Stoneback both of Allentown, Pa. January 1.

ROBERTO GUTIERREZ, to Miss Virginia Clark Wathen both of New York February 1.

VANCE QUITMAN RAWLES, Red Level, Ala., to Miss BESSIE F. COSTEN Dec. 29, 1935.

Deaths

John Joseph Thomson * Mount Vernon N Y Trinity Medical College, Toronto Ont Canada, 1902 member of the American Academy of Ophthalmology and Oto Laryngology, American Laryngological, Rhinological and Otological Society and the American Otological Society, fellow of the American College of Surgeons, aged 56 chief of the ear nose and throat department of the Lawrence Hospital, Brouville chief of the ear nose and throat department, and president of the medical board, 1915-1924, the Mount Vernon Hospital where he died, Nov 13, 1935, of hepatic cirrhosis and chronic myocarditis

William Stowe Rutledge * Ruston, La University of Alabama School of Medicine, University, 1909 also a pharmacist, past president secretary and treasurer of the Jackson-Lincoln Bi-Parish Medical Society coroner of Lincoln Parish served during the World War, aged 54, on the staff of the Ruston-Lincoln Sanitarium where he died, Dec 30 1935 as the result of injuries received when his car overturned near Brandon, Miss

Timothy Joseph Murphy * Boston, Harvard University Medical School, Boston, 1892, past president and censor of the Norfolk District Medical Society, clinical professor of medicine Tufts College Medical School, chief of staff of the Sanatorium Division of the Boston City Hospital and on the staff of St Margaret's Hospital, aged 69, died, January 1, of lobar pneumonia

Alvan Williams Atkinson * Trenton, N J Hahnemann Medical College and Hospital, Philadelphia 1893 past president of the Mercer County Medical Society, fellow of the American College of Surgeons chief, department of gynecology and obstetrics, William McKinley Memorial Hospital aged 66 died, Dec 25 1935 of cerebral thrombosis and arteriosclerosis

George W Belshe Trenton, Mo University Medical College of Kansas City, Mo, 1904 member of the Missouri State Medical Association past president of the Grundy Daviess Counties Medical Society served during the World War on the staff of the Cullers Hospital aged 54 was burned to death Dec 17, 1935, in an automobile accident

Edward James McDonough, Portland Maine Medical School of Maine Portland 1892 member of the Maine Medical Association formerly professor of obstetrics at his alma mater at various times on the staffs of the Maine General Hospital Queen's Hospital and the Maine Eye and Ear Infirmary aged 68 died, Dec 30 1935 of heart disease

Jacob Harrison Shuford, Hickory N C, University of Michigan Department of Medicine and Surgery Ann Arbor 1901, past president of the Catawba County Medical Society fellow of the American College of Surgeons served during the World War, on the staff of the Richard Baker Hospital, aged 56 died, January 15 of heart disease

Virgil David Guttard * Toledo, Ohio, Ohio Medical University, Columbus, 1907, veteran of the Spanish-American and World wars, health commissioner of Mason County, Ky for four years formerly physician to the U S Indian Service, aged 57 died, Dec 25 1935, at his home in Bowling Green of cerebral hemorrhage

Homer Clifton Oatman * San Diego, Calif, Hahnemann Medical College and Hospital, Chicago, 1895 fellow of the American College of Surgeons, aged 65, surgeon to the Scripps Memorial Hospital, La Jolla, San Diego General Hospital and the Mercy Hospital, where he died, Dec 28 1935

James Nelson Douglas, Manasquan, N J, Hahnemann Medical College and Hospital of Philadelphia, 1905 served during the World War, on the staff of the Point Pleasant (N J) Hospital, aged 60 died Dec 23 1935, of coronary occlusion and chronic valvular heart disease

Elmore E Curtis * Saginaw, Mich Bennett College of Eclectic Medicine and Surgery Chicago, 1885 for many years a member and past president of the board of education on the staff of the Saginaw General Hospital aged 74, died, Dec 22 1935 of lobar pneumonia and myocarditis

Constantine Clinton Barnett, Huntington W Va Howard University College of Medicine Washington D C 1899 member of the American Psychiatric Association formerly medical superintendent of the State Hospital, Lakin aged 66 died Dec 29 1935 of hypertensive heart disease

William Edgar Rice, Raton N M Miami Medical College Cincinnati 1891 member of the New Mexico Medical Society formerly coroner of Douglas County Ill aged 70 on the staff of the New Mexico Miners Hospital where he died January 7 of lobar pneumonia

John Joseph Gailey, Waterbury, Conn Medical School of Maine Portland, 1898 fellow of the American College of Surgeons formerly member of the city board of health obstetrician to the Waterbury Hospital, aged 72, died Dec 30 1935, of cardiovascular renal disease

Floyd Snelson Kidd, Fort Snelling, Minn State University of Iowa College of Medicine, Iowa City 1907 member of the medical staff of the Veterans Administration Facility served during World War, aged 52, died suddenly, Dec 30 1935 of coronary disease

John Francis Donohue * Oyster Bay, N Y University of Buffalo School of Medicine, 1914, on the staff of the North Country Community Hospital Glen Cove, aged 46, died suddenly January 11, in a sanatorium at Goshen of acute myocarditis

Winthrop Dodd Mitchell, Worcester Mass Bellevue Hospital Medical College, New York 1887, fellow of the American College of Surgeons, surgeon and medical director emeritus St Michael's Hospital, Newark, N J, aged 73 died, Dec 30 1935

Albert A Ghriskey, Philadelphia, University of Pennsylvania Department of Medicine Philadelphia, 1880, on the staffs of the Pennsylvania and Episcopal hospitals, aged 76 died Dec 28 1935, of arteriosclerosis and coronary thrombosis

William Carson Officer, Monterey, Tenn University of Tennessee Medical Department, Nashville 1902 member of the Tennessee State Medical Association, owner of a sanatorium bearing his name, aged 55, died suddenly, Dec 24, 1935

Edwin Wilson Ludlow, Urbana Ohio, Medical College of Ohio Cincinnati, 1883 member of the Ohio State Medical Association past president of the Champaign County Medical Society aged 74 died, Dec 29, 1935, of diabetes mellitus

John Francis Gorman, Philadelphia Jefferson Medical College of Philadelphia 1906, member of the Medical Society of the State of Pennsylvania served during the World War, aged 55 died Dec 26, 1935 of cerebral thrombosis

Egbert Laird Mortimer, Baltimore, Maryland Medical College Baltimore, 1903, member of the Medical and Surgical Faculty of Maryland, aged 63, died, January 5, in St Agnes Hospital of carcinoma of the colon

Edgar Albert Lewis, Rockport Mo University Medical College of Kansas City Mo 1905 member of the Missouri State Medical Association, aged 58, died Nov 7, 1935 in the Missouri Methodist Hospital St Joseph

John Francis Ury, Columbus, Ohio, Ohio State University College of Medicine Columbus 1935 aged 26, intern at St Francis Hospital where he died Dec 24 1935, of acute membranous enterocolitis and paralytic ileus

John Ewing Brown, Los Angeles, Jefferson Medical College of Philadelphia, 1883, formerly professor of gynecology Omaha Medical College, for many years health officer of San Pedro, aged 77, died, Dec 23, 1935

George Gansey O'Connell, Chicago, Rush Medical College Chicago 1908 member of the Illinois State Medical Society, aged 50 died, Nov 23 1935 of hemiplegia hypertension arteriosclerosis and mitral stenosis

Henry Sinclair Hutchinson, Binghamton, N Y, College of Physicians and Surgeons, Medical Department of Columbia College, New York 1893 aged 67, died Dec 25 1935 in a hospital at St Petersburg Fla

Evan C Mills, San Francisco Hahnemann Medical College of the Pacific San Francisco, 1918, aged 56, died, Dec 4 1935 of chronic nephritis cardiac hypertrophy, pulmonary tuberculosis and chronic cholecystitis

George Pratt Garland, Eunice La, Tulane University of Louisiana Medical Department, New Orleans, 1907, part owner of the Eunice Clinic and Hospital aged 53, died in December 1935 of pneumonia

Charles Warren Du Bois, Los Angeles, Cornell University Medical College New York 1927, member of the California Medical Association aged 33 was accidentally shot and killed Dec 17, 1935

Eugene Barnard Haden, Panora Iowa, University of Nebraska College of Medicine Omaha 1895 member of the Iowa State Medical Society aged 69, died Dec 24 1935 of heart disease

Don Dickinson Brooks, Connellsville Pa Maryland Medical College Baltimore 1910 served during the World War school physician aged 48, died, Dec 25, 1935, of pulmonary tuberculosis

Alice Virginia Duffield, San Diego, Calif., Hahnemann Medical College and Hospital, Chicago, 1899, aged 80, died Dec 23, 1935, in National City, of hypertension and cerebral hemorrhage.

Daniel Hiestand, Allentown, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1881, aged 79, died Dec 30, 1935, of injuries received in a fall ten days previously.

Robert L. Kern, Richmond, Va., University College of Medicine, Richmond, 1899, member of the Medical Society of Virginia, aged 64, died, Dec 24, 1935, of nephritis and myocarditis.

William Henry Leslie, St. Petersburg, Fla., Rush Medical College, Chicago, 1893, formerly a medical missionary, aged 67, died Dec 25, 1935, in a local hospital, of coronary occlusion.

George Robert Love, Preston, Minn., Minneapolis College of Physicians and Surgeons, 1910, aged 51, died, Dec 18, 1935, of hypertension, nephritis, cerebral hemorrhage and pneumonia.

Erwin L. Godfrey, Colon Mich., Hahnemann Medical College and Hospital, Chicago, 1876, Chicago Homeopathic Medical College, 1879, aged 83, died Dec 14, 1935, of angina pectoris.

Lawson A. McCurdy, Indianapolis, Central College of Physicians and Surgeons, Indianapolis, 1891, aged 74, died January 2, of bronchopneumonia and chronic myocarditis.

David Patterson Fredericks, Patton, Calif., Jefferson Medical College, Philadelphia, 1894, aged 63, died Nov 29, 1935, of a ruptured duodenal ulcer, and arteriosclerosis.

Israel Fletcher Longley, St. John, N. B., Canada, Queen's University Faculty of Medicine, Kingston, Ont., 1910, served during the World War, aged 50, died, Nov 21, 1935.

John H. Powell, Atlanta, Ga., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1893, member of the Medical Association of Georgia, aged 66, died Nov 16, 1935.

William Alexander Shearer, Rock Tavern, N. Y., Rush Medical College, Chicago, 1904, since 1928 health officer of the town of Hamptonburg, aged 58, died Dec 13, 1935.

Thomas Harris Boyle Runnalls, Carbonado, Wash., University of Oregon Medical School, Portland, 1912, aged 47, died Nov 17, 1935, at Tacoma, of pneumonia.

Samuel Nelson Miller, Middleton, N. S., Canada, University of the City of New York Medical Department, 1875, aged 85, died Dec 16, 1935, of coronary thrombosis.

John Leonidas Hobbs, Los Angeles, Marion-Sims College of Medicine, St. Louis, 1899, aged 64, died Dec 15, 1935, of cerebral arteriosclerosis and hypertension.

Florence Josephine Murcutt, Inglewood, Calif., Woman's Medical College of Pennsylvania, Philadelphia, 1907, aged 71, died, Dec 13, 1935, of a skull fracture.

Charles Alfred Hull, Liberty, Ohio, Stirling Medical College, Columbus, 1904, member of the Ohio State Medical Association, aged 59, died Dec 15, 1935.

C. W. Gleaves, Wytheville, Va., Medical College of Virginia, Richmond, 1879, also a bank president, aged 80, died Dec 12, 1935, of bronchopneumonia.

Adam M. Autrey, Houston, Texas, University of Tennessee Medical Department, Nashville, 1886, aged 72, died Dec 28, 1935, of hypostatic pneumonia.

Carl Hoffman, Seattle, John A. Creighton Medical College, Omaha, 1896, aged 63, died, Dec 1, 1935, of coronary thrombosis and chronic myocarditis.

Ellen Maria Kirk Cnemurati, New York, Medical College and Hospital for Women, 1877, aged 57, died Nov 29, 1935, of bronchitis in bedridden state.

Mary Elizabeth MacLeod, St. John, N. B., Canada, Northwestern University Woman's Medical School, Chicago, 1892, aged 83, died Dec 12, 1935.

Rutledge T. Wiltbank, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1891, aged 82, died Dec 27, 1935, of arteriosclerosis.

John Mitchiner Rumph, Titum, N. M., Southern Medical College, Atlanta, 1893, aged 85, died in December 1935, of acute yellow atrophy of the liver.

August Dutzi, St. Louis, St. Louis University School of Medicine, 1905, aged 66, died Dec 22, 1935, in the Jewish Hospital, of heart disease.

James Robert Cranford Sasser, Ga., Atlanta Medical College, 1895, member of the Medical Association of Georgia, aged 65, died Nov 29, 1935.

Stuart Calvin Runkle, Philadelphia, Jefferson Medical College of Philadelphia, 1888, aged 74, died, Dec 29, 1935, of carcinoma of the throat.

Vesselius Davis, Wapella, Ill., Western Reserve University Medical Department, Cleveland, 1882, aged 76, died Dec 20, 1935, of arteriosclerosis.

Nellie Virginia Mark, Baltimore, Boston University School of Medicine, 1884, aged 78, died, Dec 3, 1935, in Los Angeles, of acute gastro-enteritis.

David John Evans, Los Angeles, Western Pennsylvania Medical College, Pittsburgh, 1903, aged 62, died, Dec 22, 1935, of cerebral hemorrhage.

Rupert William Gliddon, St. Thomas, Ont., Canada, University of Toronto Faculty of Medicine, Toronto, 1913, aged 49, died Dec 7, 1935.

Joseph Theodore Wright, Winnipeg, Manit., Canada, Trinity Medical College, Toronto, 1901, aged 60, died, January 6, of coronary occlusion.

Edward M. Bell, Mill Spring, N. C., University of Nashville (Tenn.) Medical Department, 1896, aged 63, died, January 17, of angina pectoris.

Charles Carlyle Tatham, Edmonton, Alta., Canada, University of Toronto (Ont.) Faculty of Medicine, 1900, aged 58, died Dec 25, 1935.

August Adolph Drossel, San Francisco, Cooper Medical College, San Francisco, 1889, aged 67, died Dec 13, 1935, of cerebral sclerosis.

Elmer E. Goucher, McMinnville, Ore., Willamette University Medical Department, 1882, aged 77, died, Dec 28, 1935, of heart disease.

Anthony W. Graham, Millersburg, Ohio, University of Missouri School of Medicine, Columbia, 1876, aged 84, died, Nov 26, 1935.

Ernest Augustus McDonald, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1905, aged 57, died Dec 12, 1935.

Maurice Ernest Thomas, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1922, aged 38, died, Dec 10, 1935.

Abraham Weatherly Boyd, Chattanooga, Tenn., University of Georgia Medical Department, Augusta, 1885, aged 75, died Dec 13, 1935.

John Milton Shriver, Waynesburg, Pa., Jefferson Medical College of Philadelphia, 1880, aged 81, died, Dec 17, 1935, of heart disease.

Alberto Horatio Stockbridge, Lynn, Mass., Tufts College Medical School, Boston, 1905, aged 62, died, Dec 24, 1935, of heart disease.

Joseph Aloysius Kearns, Phelpsston, Ont., Canada, University of Toronto Faculty of Medicine, 1910, aged 50, died Dec 3, 1935.

James E. McHugh, Fort Wayne, Ind., Fort Wayne College of Medicine, 1893, aged 68, died Dec 2, 1935, in the Lutheran Hospital.

Charles Robert Cuthbertson, Toronto, Ont., Canada, Victoria University Medical Department, Coburg, 1886, died Dec 19, 1935.

Abel T. Bruere, Creamridge, N. J., Jefferson Medical College of Philadelphia, 1886, aged 79, died Dec 24, 1935, of nephritis.

Julius Gerhart Stammel, Fort Lauderdale, Fla., Medical College of Ohio, Cincinnati, 1907, aged 51, died in November 1935.

Frederick M. Sutton, Upper Lake, Calif., Atlanta College of Physicians and Surgeons, 1901, aged 57, died Dec 14, 1935.

Israel Melbourne Lovitt, Yarmouth, N. S., Canada, Harvard University Medical School, Boston, 1885, died Dec 7, 1935.

William Russell Dove, Harrison, Va., Medical College of Virginia, Richmond, 1907, aged 61, died Nov 21, 1935.

Edson W. Masten, Cato, N. Y., Albany Medical College, 1879, aged 78, died Dec 31, 1935, of chronic myocarditis.

Peter B. Robertson, Windsor, Ont., Canada, Trinity Medical College, Toronto, 1891, aged 71, died Dec 25, 1935.

Stephen Madatian Long, Fresno, Calif., Albany (N. Y.) Medical College, 1894, aged 68, died, Nov 12, 1935.

Louis Hannah, Sylva, Ga., Atlanta College of Physicians and Surgeons, 1911, aged 48, died Nov 22, 1935.

William Franklin Skillern, Hixson, Tenn. (licensed in Tennessee in 1889), aged 77, died, Dec 12, 1935.

Bureau of Investigation

CURARINA

An Alcoholic Cure-All Declared a Fraud

"Curarina," or, to give it its full name, "Curarina de Juan Salas Nieto," is a good example of the way in which the public can be swindled by 'patent medicine' exploiters when newspapers and radio stations will sell them space and time for the purpose of making the contact between the swindler and the swindled. Curarina has been sold in the United States by one Richard Diener, who describes himself as the agent for the Curarina Agency at Oxnard Calif.

Part of the advertising of this nostrum was a sixteen-page leaflet in which the alleged marvelous therapeutic virtues of this 'patent medicine' were described and testimonials were reproduced. There was also published in the same booklet what purported to be the results of a chemical examination of the preparation. It was one of those analyses that are so popular with 'patent medicine' concerns which make a pretense of frankness. The analysis gave little information regarding what was in the product but did state what was *not* in it. The examination, according to the booklet, was made by 'Dr. Frederick V. Bruchhausen O. O., Professor of Pharmaceutical Chemistry, Member of the Medicinal Committee of the University of Wurzburg (Germany)' and was from the "Pharmaceutical Institute and Laboratory for Applied Chemistry of the University of Wurzburg." It was dated January 1932. The report stated that, when observed under a quartz lamp, Curarina had "a whitish greenish-yellowish fluorescence." Further, it had a specific gravity of 0.9568, an alcohol content of 32.3 Gm in 100 cc extractives, 1.5 Gm in 100 cc ash content 0.348 Gm in 100 cc. The examination of the liquid part of Curarina to determine the "nature of the denaturant" proved negative for methyl alcohol, acetone, pyridine, bases, phthalic acid and volatile poisons. The tests for heavy metals, saponin and alkaloids were all negative. In other words, the analysis showed positively merely that it had over 30 per cent of alcohol and a small amount of extractives, and a small ash content.

The important information, of course, was that the stuff contained over 30 per cent of alcohol. This information took on added interest when one read the booklet and found that Curarina was described as 'an excellent tonic against general debility' and would stimulate the appetite 'if taken either pure or mixed with some liquor.' The idea of mixing a 'patent medicine' containing over 30 per cent of alcohol with liquor might lead one to infer that the stimulation would not be confined to the appetite.

The booklet stated that Curarina was originally invented as a "sure remedy for snake and insect bites." However, according to Mr. Diener, the California agent, "Curarina is the only remedy known today which will quickly bring a person back to normal health who is afflicted with angina pectoris and other heart troubles as well as diabetes." Mr. Diener further states that "no one ever needs to lose his arms, legs or his life from blood poisoning for by just applying Curarina full strength, and taking the medicine internally, one would recover." Further, "no person will have apoplectic strokes after using at least six bottles of Curarina."

Curarina was especially valuable according to Mr. Diener, for colds, grippe, lung and other bodily disorders, tonsillitis, tetanus and high blood pressure. It was a preventive of "malaria, yellow fever, black vomit." One teaspoonful of Curarina taken every hour would cure appendicitis and one tablespoonful every two hours was recommended for smallpox. Curarina was not recommended as a cure for cancer, but Mr. Diener said that when used in cases of cancer it reduces the pain and stops progress of such disease. Incidentally, Curarina was a wonderful preparation for 'distemper in dogs.'

One of Mr. Diener's important testimonials purported to come from 'Dr. G. F. Mendez, present Minister of Public Works of the Republic of Venezuela.' Then there were testimonials from less important people such as Mr. R. O. Thomas of Carpinteria, Calif., who heartily recommended Curarina to anyone having angina pectoris or hardening of the arteries. Mrs. Webb Wilcox of Wheeler's Hot Springs, Calif., claims to have been entirely cured of heart trouble, diabetes and kidney

trouble by the use of Curarina. Mr. E. A. Swank of Hardin Mont., reports that one of the cowboys in his locality who had "yellow jaundice" took three bottles of Curarina and was cured. Mr. H. E. Ward of Webster Groves, Mo., had a little dog with eczema which the veterinarians had been unable to cure, but it was cleared up with Curarina.

Now comes that efficient but overworked arm of the government, the Office of the Solicitor of the Post Office Department. Hon. Karl A. Crowley, Solicitor, in a memorandum addressed to the Postmaster General, recommended that the Curarina Agency and Richard Diener have the United States mails closed to them because they were engaged in conducting a scheme for obtaining money through the mails by fraudulent pretenses and promises. The Curarina Agency and Mr. Diener were notified Oct. 1, 1935, that they would be called on to show cause by November 6 why a fraud order should not be issued against them. No appearance was entered by any one in behalf of either the agency or Mr. Diener, but a written answer to the charges was submitted through Mr. Charles F. Blackstock, an attorney of Oxnard, Calif.

Mr. Crowley points out in his memorandum that Richard Diener has been engaged in the sale through the mails of a preparation called "Curarina de Juan Salas Nieto" as a cure for practically every disease known to man, to say nothing of diseases of animals. He states, further, that Mr. Diener has secured business through newspaper advertisements, radio broadcasts and by other means. He then goes into detail regarding the claims made by Diener in the material that he would send to those with whom he had got in contact by radio, newspaper or other advertising.

The federal chemists analyzed Curarina and reported that it consisted of plant extractive matter in 32 per cent of alcohol, the analysis showed the presence of potassium phosphate, chloride, sulphate, carbonate and a small trace of all aloids, with tannin and saponin indicated. The plants from which the extractives were taken had no recognized value in modern medicine as a remedy for any disease whatever. The Solicitor learned from physicians and veterinarians who were competent to express an opinion that Curarina had no essential value either as a palliative or as a curative agent. Mr. Crowley pointed out that Mr. Diener, who was promoting the stuff, is not a physician and has no medical training. In fact, Diener is said to have admitted to the Post Office inspector who investigated the matter that he does not even know the ingredients of the preparation and that he is wholly unqualified to pass on symptoms of diseases or to state how the alleged therapeutic effects would be accomplished.

In view of all the evidence, Solicitor Crowley recommended that a fraud order be issued. Postmaster General Farley on Nov. 11, 1935, closed the mails to the Curarina Agency and Richard Diener.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE: The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

Albert's Food—Albert's Food Laboratories, Hollywood, Calif. Composition: Essentially wheat flour, shorts and bran. Body builder etc. Fraudulent therapeutic claims.—[N. J. 23020, April 1935.]

Ammon's Antiseptic Wash—Home Remedy Co., Pittsburgh, Pa. Composition: Essentially plant drug extracts and water, accompanied by a box of suppositories consisting essentially of boric acid, ammonium alum, fats and waxes. Not antiseptic when used as directed. Fraudulent therapeutic claims.—[N. J. 23255, May 1935.]

Pheno Isolin—Scientific Mfg. Co., Scranton, Pa. Composition: Essentially turpentine, camphor, menthol and resin dissolved in an oil. For boils, carbuncles, ulcerated cancer, neuritis, coughs, etc. Not a ready germicide or an antitoxin as represented. Fraudulent therapeutic claims.—[N. J. 25230, May 1935.]

Correspondence

OXYGEN TREATMENT

To the Editor —The dramatic recurrence of a situation that has become a dangerous one occurred recently and prompts me to write this letter

A child, aged 9 years suffering from bronchopneumonia, was in an oxygen tent at a well known hospital in New York. I was asked to see the child in consultation although the doctor told me when I arrived that it seemed to be of no use. The child was as blue as a blue serge coat, the pulse was 160, the temperature 108. Although the child had been in a tent, the nurse said that he had been blue all day. The oxygen concentration in the tent was 28 per cent. Although it seemed quite hopeless, I increased the oxygen flow by adding an extra tank and ran in 32 liters of oxygen per minute until the concentration rose to 60 per cent. The child's color immediately began to improve and the pulse began to fall; the improvement continued until the pulse came down to 120, the temperature gradually falling to 101, and the child, whose eyes had previously rolled upward, became conscious. The breathing, which had appeared terminal and very shallow, took on a deeper and more vigorous character.

The point which this illustrates is that a number of oxygen tent manufacturers have sold tents saying that it is unnecessary to test the oxygen concentration if a certain flow, between 7 and 12 liters per minute, is run in. In many instances the tent leaks to such a degree that the recommended flow will give a concentration of less than 30 per cent. In three other instances in hospitals in New York I have found that between 30 and 40 liters per minute was necessary in order to keep the oxygen concentration between 50 and 60 per cent. In two instances the cover of the icebox made so little contact, owing to worn out rubber gaskets, that the oxygen escaped in this way. In a third instance the water bottle top at its connection with the glass leaked to such an extent that very little oxygen was actually entering the tent.

In one hospital in which I was for a time the medical consultant, disappointment with oxygen therapy could be traced to a practice of giving 7 liters a minute of oxygen in a tent that leaked like a sieve. In these various instances which I quote there was no testing of the oxygen concentration within the tent. This procedure, which takes a minute and a half to do even of course be learned in a half hour by almost any attentive individual, and it seems almost criminal to me to witness hundreds of times an oxygen tent being prescribed without any prescription of dosage. In the various articles which I have written on this subject I have attempted to emphasize that the dose of oxygen be prescribed and not simply an oxygen tent, and that the oxygen concentration be tested either by a technician, a nurse or the doctor himself at least three times during the day. In many instances, for example, of congestive heart failure, a diuresis does not set in unless the oxygen concentration is raised to 50 or 60 per cent.

I think the importance of prescribing the dose of oxygen should be emphasized in medical school teaching. Benish of the Linde Air Products Company, informs me that in hundreds of instances of tent usage throughout the country it is uncommon to have the oxygen concentration within the tent actually tested. This matter impresses me as a very serious one. The nasal catheter with the method which I suggested of putting the catheter in the nasopharynx and running in from 4 to 5 liters of oxygen a minute will give a concentration of 38 per cent, which is higher than that frequently obtained in a poorly run oxygen tent. Employing the modification of that method by which the catheter is put in the oral pharynx Wineland and Waters have obtained concentrations of 50 per cent in the inspired air.

The oxygen tent in which the air is cooled and dried may become a therapeutic procedure of crucial value provided the oxygen concentration is elevated above 50 per cent and in some cases for periods of ten to twelve hours to as high as 90 per cent.

Sayers in unpublished work, shows that animals can live in pure oxygen sixteen hours a day without harmful effects. I have confirmed Sayers' work but have also shown that if animals are kept in 50 per cent oxygen instead of air the remainder of the time pulmonary edema develops. However it appears safe from animal experiments to administer from 90 to 100 per cent oxygen for ten to twelve hours a day and 50 per cent oxygen the rest of the time. This work I have mentioned in an article on the therapeutic use of helium in the December *Annals of Internal Medicine*. I mention it because there was in that article an example of an infant that had sudden bilateral pneumothorax in which the dyspnea was relieved only when the oxygen concentration in the tent was raised to 90 per cent.

It seems to me therefore, that emphasis on the importance of prescribing the dose of oxygen namely the oxygen concentration desired, could profitably appear. Necessarily, no tent should be used unless the oxygen concentration is tested as a routine. At the present time it is safe to say that over 90 per cent of the oxygen tents in use in the United States are not tested for the oxygen concentration within the tent.

In the use of helium it is obvious, as I have mentioned in the article referred to, that the dosage of helium employed is of even greater importance, and I think it would be unfortunate to have helium used by any one who is not equipped to determine the amount of oxygen in a helium oxygen atmosphere.

ALVAN L. BARACH, M.D., New York

FIRST SURGICAL OPERATION ON THE HEART

To the Editor —In the Correspondence column of THE JOURNAL Sept 7, 1935, is a communication from Dr Charles H. Garvin of Cleveland calling attention to the fact that on July 9 1893, Dr Daniel Hale Williams, Negro surgeon of the Provident Hospital in Chicago, performed a successful surgical exploration of the heart for a stab wound. Dr Williams later recorded his case in the *New York Medical Record* (51:437 [March 27] 1897) under the title "Stab Wound of Heart and Pericardium." Dr Garvin was stimulated to write this article after reading a report by Drs George Benet and Charles Spivey in the June 1 issue of THE JOURNAL because these physicians stated that "the first recorded attempt to suture a stab wound of the heart was made by Cappelen in 1895."

Dr Garvin has further stated in the leading editorial of the November 1935 issue of the *Journal of the National Medical Association* that Dr Williams "takes priority in successful operation for stab wound of human heart."

Since Dr Benet's statement rested on information derived from me I feel it proper to call attention here to the fact that Dr Daniel Williams in his own report of his case stated that "there was no hemorrhage from the heart or pericardium." Dr Williams then proceeded to close the wound in the pericardium having found no wound in the heart. The hemorrhage apparently came from division of the internal mammary vessel. In view of this and in view of a study of Cappelen's original report (*Norsk mag f Læge idensk* 11:285 1896) it seems only fair to give to Cappelen priority in making a deliberate attempt to suture a wound of the heart.

I cannot give accurate data concerning first attempts to suture wounds of the pericardium, in which category Dr Williams' case belongs but it is known that Romero of Barcelona as early as 1819 practiced pericardiostomy for pericarditis (see

Baizeau *Memoire sur la ponction du pericarde au point de vue chirurgical*, *Gaz de med et de chu*, Paris, 1868, p 565) It is indeed possible and from my historical researches probable that the case reported by Dr Williams was the first case in which the pericardium was sutured for a wound

ELLIOTT C CUTLER, M.D., Boston

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but the name will be omitted on request.

CONSTIPATION IN CHILDREN

To the Editor—I have under my care a five year old youngster who has had clay colored stools for the last three years. The stools are of the constipated type—small marble like lumps. The bowels are moved once daily. Treatment has been of no avail. Please advise as to cause and treatment. Physical examination otherwise is negative.

M.D. New York

ANSWER—Constipation in a 5 year old child, accompanied by no impairment in health has been termed simple constipation. The most common cause is faulty early training. If the habit of regular defecation is not early established the infant or child will develop this symptom. Other causes that may be mentioned are errors in diet, especially excessive fat causing soapy stools, deficiency of tone in the abdominal or intestinal muscles, a deficient secretion of intestinal juices, and lack of water. In certain individuals of a nervous type or temperamental character the habit of constipation is more frequent. Organic causes such as stenosis of the anus or rectum, spasm of the sphincter muscle, fissure of the anus, or rectal polyp must be considered. Spastic constipation is rare in childhood.

The treatment consists in establishing regularity in habits of defecation. In the older child it may be advisable to diminish the quantity of milk and increase the supply of pulpy fruits and vegetables in the diet. Coarse cereals containing bran may be added, and the malt sugars may be substituted for sucrose. Honey and molasses are often used with good effect. A dose of liquid petrolatum at night in obstinate cases is often indicated, and a preparation of liquid petrolatum with agar is sometimes more effective than the oil alone and has the added advantage that it is not usually passed unconsciously as is the oil, thus avoiding staining of underclothing. Plenty of water between meals is recommended. The most important factor is training the child into a regular habit. A definite time should be fixed, most preferably immediately after breakfast. By proper instruction, the child must be taught to acquire the habit of going to stool and of starting his own evacuation by correct muscular coordination. Any organic defect that might be a cause of the constipation should be suitably remedied.

SKIN REACTION WITH ARSENICALS

To the Editor—Will you kindly tell me which are the characteristics of the skin reactions due to trivalent and to pentavalent arsenicals and possibly the literature on the subject?

M.D. Rhode Island

ANSWER—Inorganic arsenic, whether trivalent or pentavalent produces in most cases as evidence of acute poisoning an erythema sometimes described as erysipeloid or scarlatiniform. Urticaria and papular eruptions also are described. Less often it causes vesicular, bullous or even ulcerative eruptions. Herpes zoster is occasionally reported as a sequel of acute poisoning with arsenic.

Chronic poisoning with inorganic arsenic is much commoner, taking the form of pigmentation of the skin of a dirty gray or yellowish brown color, distinguished from the pigmentation of Addison's disease by not affecting the mucous membranes. The face, neck, axillae and abdomen are involved first. By far the commonest evidence of chronic poisoning by arsenic is the keratosis papular and localized on the palms and soles. It begins about the sweat ducts but later may cause diffuse thickening of the whole area. This keratosis is an important lesion, for it not seldom ends as a malignant, prickle cell epithelioma.

Similarly there is no strict division as concerns skin eruptions between the trivalent and pentavalent organic arsenicals. While the trivalent arsphenamine group is better known as a producer of various skin eruptions, this unenviable reputation is likely to be soon cast in the shade if the use of the penta-

valent acetarsone continues to increase, for it causes similar eruptions in from 25 to 7 per cent of the cases in which it is employed, far exceeding the frequency of dermatitis caused by arsphenamine.

J. E. Moore (The Modern Treatment of Syphilis, Springfield Ill., and Baltimore, C. C. Thomas, 1933, p 79) divides these eruptions into sensitizing and nonsensitizing. Urticaria occurs commonly as part of the nitritoid reaction, but a scarlatiniform erythema may take its place. These subside as the reaction passes, whether consequent to the intramuscular injection of epinephrine or without it.

Along with the febrile reaction occurring so frequently after the first or second injection of one of these drugs, an erythematous or urticarial eruption may appear. This subsides with the fever and ordinarily does not recur after subsequent injections. There is not much itching with these eruptions. In place of them, herpes zoster or herpes simplex may occur.

H. S. Keim (Erythema of the Ninth Day, *Arch. Dermat. & Syph.* 31:291 [March] 1935) has recently revived interest in Milian's conception of an erythema occurring on the ninth or tenth day after the first injection of any of the arsphenamines. In his series of ten such cases, one had to be excepted because of a mild leukopenia and later a slight icterus with pruritus and increase of bilirubin in the blood stream. With this exception, the eruptions were scarlatiniform or morbilliform but lacked symptoms allowing their classification as real measles or scarlatina as Milian thought them. Considerable fever, up to 105 F. in one case, accompanied the eruption, and pharyngitis, stomatitis, vomiting and photophobia occurred in different cases. The reaction is due to some part of the drug, though Keim thinks possibly not to its arsenic.

It is a self-limiting reaction in spite of continued administration of the medicine clearing in three or four days. Itching is slight. The eruption appears usually on the trunk and extremities first. The superficial lymph glands are usually enlarged. It occurs mostly after mild dosage and in younger patients. Women are more liable than men to develop it.

The fixed eruption is due to a localized sensitization to one of the arsphenamines. It appears as a single plaque or a few of them, oval or round, pink, yellowish or brownish red. As it subsides in a few days to a week, pigmentation is often left. Following the next injection the same area reddens and swells and several similar ones appear, passing through the same evolution. In severe cases these may be bullous. They seldom are of importance if the use of the drug is discontinued.

Of much greater importance are the eruptions occurring late in the course of injections and beginning usually on the limbs as a very itchy macular morbilliform, papular, often lichenoid, vesicular or squamous rash. They may appear at any time from two hours to three weeks after the last injection of the drug, on the average on the fifth day. They become very scaly and spread to involve the whole body, then they are known as exfoliative dermatitis. Mild cases may never become generalized and may clear up in a few days. More often they last three weeks or longer and are accompanied by constitutional symptoms, fever, chilliness, prostration, albuminuria and icterus. The mucous membranes may be involved, and there may be stomatitis, vaginitis, exfoliative conjunctivitis, diarrhea with epithelial cells and mucus in the stools, and temporary deafness from plugs of scales in the ear canals. This is a real sensitization, usually a group sensitization, so that any drug of the group will react on the skin.

Following this there is a great liability to skin infection. Boils, carbuncles, due both to vulnerability of the skin and to lowered general resistance and sometimes agranulocytosis, acute bronchitis and polyneuritis may occur.

Purpura is seen less often during or after a course of the trivalent organic arsenicals but is a most important symptom. Its appearance should be immediately followed by a complete blood count. If the red or white blood cells decrease markedly in number or the percentage of polymorphonuclear neutrophils falls, the medication must be stopped at once. This condition, agranulocytosis is often accompanied by a stomatitis or angina in which the fusospirochetosis organisms are frequently found. It differs from the stomatitis due to mercury in being more acute, more red, drier and more exfoliative rather than moist, fetid and spongy as is the mercurial form (Stokes, J. H. Modern Clinical Syphilology, ed 2, Philadelphia and London W. B. Saunders Company 1934, p 470).

Reactions to bismuth arsphenamine sulfonate are of the same nature as the foregoing, modified by the action of bismuth which is an adjuvant in the production of stomatitis and dermatitis.

Few skin reactions to mapharsen have been reported but pruritus and exfoliative dermatitis have occurred.

Acetarsone (known also as stovarsol or spirocide) is gaining in popularity because of the ease of its administration, but its toxicity seems much greater than that of the arspenamines, perhaps because of unwise administration. It may be responsible for the severest skin reaction, exfoliative dermatitis or agranulocytosis, which is apt to be accompanied by purpura. As much care is needed in its use as in the administration of any other organic arsenic compound.

Jaundice during a course of any of these drugs should be an indication for ceasing medication. It is usually of the catarrhal type, with a slightly swollen liver, its tender edge from 2 to 6 cm below the edge of the ribs, bile pigment in the blood and the urine but absent from the stools, and a short febrile course. It occurs from a few days to several months after treatment. Acute yellow atrophy occurs most often in the pregnant.

Tryparsamide is the only one of the commonly used organic arsenicals that does not cause skin eruption. The following are recent articles:

Ayres Samuel Jr and Anderson N P. Cutaneous Manifestations of Arsenic Poisoning. *Arch Dermat & Syph* 30 33 (July) 1934.
Wile U J and Sams W M. Jaundice in Syphilis. Relation to Therapy. *Am J M Sc* 187 297 (March) 1934.

CARCINOMA OF VOCAL CORDS

To the Editor—A white man, aged 60, complains of hoarseness of nine months duration. Indirect laryngoscopy reveals paralysis of the left cord. Direct laryngoscopy shows fixation of the left cord and left side of the larynx with a tumescence and slight redness of the sinus of Morgagni. A piece of the cord removed for biopsy confirmed the diagnosis of carcinoma of the larynx. There are no externally palpable glands. The general physical condition of the patient is good. What is the treatment of this case—surgery, x-rays or radium? What are the statistics with each form of treatment?

M D New York

ANSWER—Carcinoma of the vocal cords may be classified from the standpoint of prognosis and operability somewhat as follows:

1 Those cases in which the cord is involved in its middle third and the cord remains freely movable.

2 Those cases in which the cord is usually fixed, the growth not extending much beyond the median line anteriorly and not encroaching on the posterior third of the cord to any extent.

3 Those cases in which the carcinoma involves the entire vocal cord from the arytenoid posteriorly to the median line or beyond anteriorly.

4 Cases belonging to groups 2 and 3 with the thyroid cartilage involved additionally or with encroachment on glands in the neck.

Group 1 is the earliest form and offers an excellent prognosis if treated by splitting the larynx (so-called thyrotomy or laryngofissure) and widely removing the affected cord. This is the treatment of choice in the opinion of the most competent laryngologists in this country, Chevalier Jackson and his school and Sir St Clair Thomson in England and others obtain as high as an 80 per cent or greater incidence of lasting cures in this type of case.

In group 2 good results may be obtained by means of this procedure, but the number of lasting cures will be less and the number of recurrences will be greater.

In group 3 thyrotomy is no longer suitable. Such patients should have a total laryngectomy. The operative mortality and morbidity is much higher than in the operation spoken of and the prognosis for lasting cure is much less.

In group 4 the outlook becomes even worse, no matter what the treatment.

As to radium and x-rays a few experts have reported that in group 1 they have obtained results almost as good as those to be had by operation. They say, furthermore, that the patient is spared an operative intervention and that in the event the disease process is not controlled operation may still be undertaken.

In group 2 it is a debatable question whether operation is better than radiation therapy. The majority of competent laryngologists in this country lean toward the idea of the operative type of intervention.

As concerns group 3 the tendency may be even more to lean toward the use of radium and the x-rays although the whole field is still controversial. A cure by the use of radiation methods spares the patient the risks and the permanent disabilities that follow total removal of the larynx.

If operation should be performed in cases falling in group 4 a wide dissection of the glands of the neck would be required in addition. As a matter of fact the tendency is not to rely in the more advanced cases solely on surgery or radiation

therapy but on combinations of the two. The manner and form of these combinations depend on the individual operator and the means at his disposal.

As to statistics, in cases belonging to groups 2, 3 and 4 it is not possible to make accurate statements. They vary with the different operators, and in the field of radiation therapy the time is as yet not long enough to speak with final authority.

CLIMATE FOR BRONCHITIS AND BRONCHIECTASIS

To the Editor—I am 33 years of age and have been bothered with a maxillary sinus infection for three or four years. I have been in western Texas for two and one-half years and since coming out here I have developed a chronic bronchitis which has gradually become worse. Injection of iodized oil into my bronchial tubes recently showed considerable bronchiectasis. I had a submucous operation about a year ago and since that time haven't had any acute sinus attacks. A specialist reports my sinus in very good condition at the present time. The climate here is dry and the elevation is 2900 feet. I am a company doctor for an oil firm and there is considerable sour gas in the camp particularly on still nights. My cough and general condition have been I am sure greatly aggravated by this gas and by the dust we have in this part of the country. Other doctors have recommended but little in the way of treatment except a change of climate and use of autogenous vaccine. I tried the vaccine last year and have also tried a stock vaccine without any apparent benefit. I get a marked reaction to both vaccines. I would like your opinion on the kind of climate and the parts of the United States that are most favorable to a chronic bronchitis and bronchiectasis. I would appreciate any suggestions you could offer in the way of treatment. I am robust and healthy looking but have become very toxic and I am hardly able to do my work. A thorough check up has found nothing wrong with me except the bronchitis and bronchiectasis. Please omit name.

M D Texas

ANSWER—It is impossible to suggest any locality that would be of certain benefit and there is nothing except climate which really offers any probability of help. It would be advisable to take some time to investigate personally localities that are removed from the oil fields. The dust will be somewhat difficult to avoid in the Southwest but in cases of bronchiectasis the disadvantage of occasional dusty days are slight when compared to the advantage of an equable, warm, dry climate. A dry air is not necessarily a desideratum, and some patients do well on the seashore. Some place on the Pacific coast or in Florida might be considered. Many patients do very well in Florida. In such a case the question of dust from molds must be considered.

BELL'S PALSY

To the Editor—1 Of what value are the faradic and galvanic current tests in determining the prognosis of an ordinary case of Bell's palsy? 2 How long should one wait before advising operative intervention? 3 What if any are the indications for surgery in this condition? 4 What are the usual surgical procedures now employed? Please use initials only in answering.

M D New Jersey

To the Editor—I have under my care a man aged 54 who has a left sided Bell's palsy. At the appropriate time I plan to treat him with galvanic stimulation followed by faradic stimulation. What intensity of stimulation should I use in the early course of treatment? What duration of each early stimulation? What frequency of treatment? How long should the treatment continue? Please omit name.

M D Illinois

ANSWER—1 In a case of Bell's palsy the faradic and galvanic currents are used in order to determine the presence of a reaction of degeneration in the involved facial nerve. For example if the muscles and nerve of the affected side react to faradic and galvanic currents, one may say that the paralysis will disappear in about six weeks. If the muscles and nerve do not react to the faradic but react abruptly or slowly to the galvanic current, it may be said that the paralysis should disappear in from six to eight months. If however there is no reaction to either the faradic or the galvanic current, one may say that the facial nerve is so involved as to appear to be anatomically interrupted.

2 One should wait at least eighteen months and only after sufficient treatment to the involved side has been given in the form of galvanic current and massage.

3 The indications for surgery are usually severe ectropion or marked deformity of the mouth and cheek.

4 The usual surgical procedures are an anastomosis with the cut ends of the facial nerve, anastomosis of the facial and hypoglossal nerves or anastomosis of the facial and spinal accessory nerves.

The length of time necessary for the treatment of Bell's palsy is dependent on the reaction of the involved facial muscles and nerves. From ten to fourteen days after the onset of a facial paralysis (Bell's) the involved muscles should be tested with the faradic and the galvanic current to determine

the presence of a reaction of degeneration. One must use only sufficient galvanic or faradic current to produce a contraction, and this should be continued for from eight to twelve minutes three times a week. The length of time of treatment depends on the response of the involved muscles to the galvanic and the faradic current. Light massage to the involved facial muscles should be carried out twice daily for five minute periods. Occasionally a contracture of the involved musculature will develop in a case of Bell's palsy. In these cases it is wise to dispense with all treatment for at least four weeks.

ANGINA PECTORIS

To the Editor—I have under care a patient who is being treated for angina pectoris (a typical case). His symptoms are (1) blood pressure 170 systolic 95 diastolic (2) heart slightly decompenated with occasional moist rales posteriorly pulse 96 and regular (3) attacks of angina of moderate severity which occur following effort of any sort emotional strain or going out into the cold air. The pain radiates to the left shoulder and down the left arm. His treatment has been as follows (1) sodium nitrite (2) theocaine (3) theophylline (4) tincture of iodine (5) glyceryl trinitrate (6) phenobarbital and (7) digitalis. Diet and general care have been advised. The foregoing treatment has been found insufficient. My purpose in writing is to inquire whether you have any information as to whether or not sodium chloride 5 per cent (sterile and distilled) intravenously has ever been used here. I have used the saline injections for endarteritis obliterans (Buerger's) disease with excellent results. Although not specific the good results are thought to be due to (1) increased blood volume and (2) lessened blood viscosity (Beckman). Both these effects would be highly desirable in coronary disease. Do you think that sodium chloride is contraindicated here because of the arteriosclerosis? Please omit name if published.

M D New York

ANSWER—No record of the use of intravenous sodium chloride is available. Any possible beneficial effects would be transitory. Such a procedure would doubtless increase the blood volume for a period the length of which would be determined by the ability of the kidneys to get rid of the excess fluid or sodium chloride. It would probably do more harm than good and possibly harm that could not be undone. The chances of any real or permanent advantage are negligible.

Of the medicines already tried, the theocaine or theophylline, with or without the phenobarbital used over long periods and in adequate dosage, appear to offer the best chances of benefit. The sodium nitrite may lower the blood pressure enough to decrease the coronary flow, and the glyceryl trinitrate should be used only to relieve attacks. Digitalis may have enough of a vasoconstrictive effect on the coronaries to offset any possible advantage and should be used very cautiously and critically. Unless there are specific indications, it is best not used at all.

TREATMENT OF SPASTIC PARALYSIS

To the Editor—Miss D. P. aged 18 had infantile paralysis during infancy her parents do not know at what age. They became aware of it when she attempted to walk. Now her right limbs are somewhat atrophic and spastic. Early in childhood she developed slight brief seizures. These consist of talk which does not make sense, a post-encephalitic gait and expression and periods of excessive elation and depression. She also has major convulsive attacks which are always preceded twenty-four hours or less by foul putrid breath and these major attacks are followed by several minor attacks. The foul breath clears in four or five days and with it the attacks which are repeated at irregular intervals. She eats nothing for two days during the foul breath period. She has been treated as a metabolic and epileptic case. Since two blood sugar tests gave a reading of 72 and 75 mg per hundred cubic centimeters and most of the attacks came several hours after meals and before breakfast hyperinsulinism was suspected but treatment under this theory was not effective. Do you consider the cause of the foul breath the cause of the epileptoid attacks? Attempts to aid digestion and elimination have yielded no adequate result.

M D Illinois

ANSWER—The fact that the right limbs are spastic suggests that the lesion giving rise to the palsy was located in the brain and was not what is usually called infantile paralysis or, better, anterior poliomyelitis. The cerebral lesion would account for the encephalitic type of gait and expression and probably also for the occurrence of epileptic seizures. It is possible also that the cerebral damage may have resulted in disturbance of the vegetative functions of the body. In this sense the epilepsy and the digestive disturbances would be due to a common cause, this is a different view from that which would ascribe the seizures to the digestive upset. Therapy in such cases unfortunately is often of little value. A careful neurologic study is indicated for possible localizing signs. A ketogenic diet is worth trial and should it prove of no advantage, one can do little more than advise general hygienic management with the administration of anticonvulsive remedies such as phenobarbital.

EMPHYSEMA

To the Editor—March 24 I saw a boy 15 years of age and weighing 250 pounds (113 Kg) who had been having a streptococcal sore throat for several weeks. A few days later he developed group IV pneumonia. He was hospitalized and several days later developed scarlet fever. Complications set in in the form of acute nephritis, dilatation of the heart and myocarditis. Also an empyema of pneumococcal origin developed. The latter was aspirated and usually about 2000 cc of pus was obtained. Aspirations were continued for several weeks until it became very difficult to aspirate. May 5 a rib resection was done and the pus evacuated. It was found thinner than expected. A few days later irrigations of the chest cavity were begun with dilute solution of sodium hypochlorite. At the present time the tube is still in the chest cavity with the end in an antiseptic solution in a bottle beside the bed. Little pus is obtained and that perhaps once a day or every other day. Roentgen examination of the chest shows no expansion of the lung. For several weeks after the rib resection the boy blew water through Woulfe bottles but in the past few weeks he has not done so complaining of being dizzy and having a severe headache whenever he blows. He has steadfastly refused to resume the exercise. What other exercise would you advise? His temperature has been normal for the past five or six days but it takes spurts and may go up to 102. His pulse varies from 100 to 120 and his respirations from 20 to 24. What procedure would you advise? Would you remove the drainage tube? Kindly omit name and address if this is published.

M D New York

ANSWER—Since the lung has not expanded after a number of weeks of treatment, and since there are occasional bouts of fever, inadequate drainage of the empyema cavity or a broncho-pleural fistula should be considered as possible factors responsible for the chronicity of the condition. If the drainage tube is not on the very floor of the empyema cavity (as determined by probing with a uterine sound or by roentgenograms made after the injection of iodized oil or 15 per cent sodium iodide solution into the cavity) or if the tube is farther forward than the posterior axillary line, the patient should be operated on again to establish completely efficient drainage. The caliber of the drainage tube should be sufficiently great to prevent its occlusion by secretions and the inner end of the tube should be neither too far in the empyema cavity nor buried in the thoracic wall.

Since the patient has recently had evidence of myocarditis and cardiac dilatation, exercises such as those with Woulfe bottles should not be used because of the load that they place on the cardio-circulatory functional reserve.

If in spite of several months of efficient drainage the empyema cavity should fail to become obliterated, and if the patient's heart and kidneys are then in satisfactory condition some effective combination of extrapleural and subsequent Schede thoracoplasty should be considered.

ASPERMIA

To the Editor—A strong vigorous man aged 34 a farmer married eight years has normal sexual desire and normal erections and indulges in the sexual act on an average of once each ten days but never has experienced orgasm or ejaculation during coitus. However about once in every two or three months he experiences nocturnal pollution with some degree of pleasurable sensation. He had no sex experience before marriage and consequently has never had any type of venereal disease. The personal and family histories are negative. The wife appears normal in every way. What pathologic condition can be back of this condition? What line of treatment would be suggested? What in your opinion is the prognosis?

M D Nebraska

ANSWER—This is an interesting and rather rare condition termed aspermia (lack of expulsion of semen) and is to be distinguished from azoospermia (absence of spermatozoa in the semen). The orgasm or height of the voluptuous feeling is due to the squeezing of the seminal fluid through the ejaculatory ducts, and when this process is absent there can be no orgasm. This explains why during pollution there is some pleasurable feeling.

The condition is due to an obstruction either in the ejaculatory ducts themselves or to their openings into the prostatic urethra. It may also be due to an abnormal nervous mechanism of coitus in which case the semen instead of progressing outward toward the meatus is regurgitated into the bladder. It is therefore important to examine the urine after coitus for seminal fluid (including spermatozoa). The faulty mechanism may be brought about by the patient training himself to retard ejaculation either while spooning or during coitus. The obstruction in or about the ejaculatory ducts may be the presence of strictures or bands in the neighborhood of the opening or even a slight congestion in the prostatic urethra at the ejaculatory openings sufficient to cause swelling that obstructs the openings.

The diagnosis of the obstructive cases can be made by a cysto-urethroscopic examination observing the openings and, in rare

cases, catheterizing the ducts and if necessary injecting them and having a roentgenogram made. The nervous cases can often be diagnosed by finding spermatozoa or other seminal elements in the urine after coitus.

The treatment depends of course on accurate diagnosis. In cases in which there is merely congestion about the openings, gentle prostatic massage and instillations of weak silver nitrate solutions (from 1:3,000 to 1:500) in the prostatic urethra with the Bangs sound syringe will effect a cure. In cases of strictures of the ducts, gentle catheterizing of these through the urethroscope will effect a cure. In the case under consideration the presence of pollutions at times would seem to indicate that there is no permanent organic obstruction and therefore the mild measures mentioned should effect a cure. The patient must however avoid anything that might bring about unnatural congestion in the prostatic urethra, such as prolonged spooning and coitus interruptus.

TINNITUS AURIUM

To the Editor—A man aged 32 apparently in good health has been troubled by a continuous tinnitus aurium for the past two years. Physical examination including that of the eustachian tube and ear drum was negative. There is no history of vertigo or syncope accompanying this condition. In the past year a diagnosis of an irritation at the orifice of the eustachian tube has been made by three competent eye, ear and nose specialists. Treatment by one of the specialists was to inflate the eustachian tube on alternate days for fifteen treatments by another to deflate the eustachian tube on alternate days for fifteen treatments the third specialist had the patient on calcium for fifteen days all with out avail. Thinking that it might be a labyrinth involvement I injected one twentieth grain (0.003 Gm.) of pilocarpine hydrochloride daily for five doses with no results. Foreign protein therapy was also resorted to but with no results. I should like to ascertain the cause and treatment for such a condition.

M D Wisconsin

ANSWER—Tinnitus aurium may be caused by a great variety of lesions of the outer, middle or inner ear and occasionally by intracranial conditions independent of the ear, such as aneurysm. Treatment is effective only when the tinnitus is the result of a condition that can be directly relieved, such as impacted cerumen in the outer canal, traumatic perforation of the drum membrane, acute occlusion of the eustachian tube (in which case a single inflation will give immediate relief but a series of inflations may be necessary to maintain the patency of the tube), suppurative otitis media, toxic labyrinthitis the result of focal infection, neuritis of the eighth nerve from drugs (i.e., acetylsalicylic acid and quinine), acoustic neuroma, and syphilis of the inner ear.

Common causes for tinnitus that cannot be influenced by treatment are otosclerosis (in which the tinnitus may antedate the onset of the deafness by several years and there is often a family history of deafness), senile nerve deafness, degeneration of the organ of Corti the result of acute trauma from a sudden loud noise in the ear such as an exploding firecracker, primary nerve deafness of unknown etiology, and secondary degeneration of the eighth nerve the result of chronic suppurative or non-suppurative otitis media.

When the tinnitus is due to any one of the latter group symptomatic treatment alone is of avail and consists of the administration of small doses of a sedative such as phenobarbital from 0.016 to 0.03 Gm., three times a day.

Most cases of severe tinnitus tend to subside with the passage of time.

INDUSTRIAL DISEASE IN HOSIERY INDUSTRY

To the Editor—What industrial diseases are common in the manufacture of hosiery? Can you furnish me a bibliography on this subject?

M D Pennsylvania

ANSWER—No industrial diseases are common in the manufacture of hosiery but a few occasionally arise their nature depending in some measure on the type of stocking whether silk rayon, cotton or wool. Many of the conditions that have been encountered do not constitute characteristic occupational diseases but rather are the vague results of monotony, noise, vibration and lack of adequate plant sanitation. For example, suicide rates have in times past been considerably higher in this branch of industry than in industry in general and apparently rates are higher for hosiery manufacture than for other branches of the textile industry. At once it is to be noted that present conditions are much superior to those of a generation ago. The literature that has developed around this pursuit scarcely applies to present-day conditions and to some extent may be ignored except for historical purposes. Noise may be the source of occupational deafness or of neuroses. Certain classes of machines lead to tenositis and to related inflammatory disorders of the hands and forearms. The frequency of tuberculosis is believed to be high which in times past has been linked with dusts. Perhaps a greater significance (than

is attached to dust as the specific cause) may be given to general work environment, home conditions and low wages. Varicose veins have been attributed to long standing in machine tending in this industry, but it is here recognized that continuous standing is perhaps less injurious than continuous sitting, and that neither is desirable as a continuous practice. Anemia has been reported, but again this may be traced to no specific cause and is known to be common to many branches of the textile industry.

Weston in 1927 established that ocular fatigue was at that time prevalent in the hosiery industry. With the substitution of aniline dyes for mineral dyes the occurrence of lead or arsenic poisoning has largely disappeared. However the dyes as now used, together with agents for lustering, delustering, sizing and bleaching, may give rise to skin diseases in those establishments carrying out such operations. The wearing of hosiery has led to injury caused by dyes (Schwartz, Louis *Pub Health Rep* 49 1176 [Oct 5] 1934). It follows if the wearer of socks incurs damage that the maker of these same socks may be exposed to some extent. In "scrooping," finishing, waterproofing and lustering a variety of chemicals may be used including sulfonated oils, special soaps, acetic, formic and tartaric acid, gums, gelatin, waxes, paraffins, zinc sulfate, barium sulfate, aluminum sulfate, borax and sulfonol. Persons may become sensitized to various of these substances so that limited exposure may be followed by a dermatitis. Extensive information of the hazards of the textile industry including the manufacture of hosiery may be found in the International Labor Office publication "Occupation and Health" 2 1031. There a bibliography may be found which, however, chiefly centers about foreign languages.

TREATMENT OF SYPHILIS—TONSILLECTOMY

To the Editor—A woman aged 31 married a housewife had a miscarriage two years ago after having been married for one year. She was then discovered to have syphilis which from subsequent investigation she probably had had for six or eight years (after her first marriage). She was given apparently vigorous antisyphilitic treatment following her miscarriage mainly by intravenous arsenicals. Eight months ago because of pelvic symptoms she had an operation and according to the patient had one ovary both tubes and the appendix removed. Continued antisyphilitic treatment followed the operation. Six months ago she had marked edema of the legs, hands and face. She was told that the urine contained albumin and that she had kidney trouble. She was placed on a diet and antisyphilitic treatments were stopped. Two weeks ago I saw her. At present she complains of hot flashes, palpitation and frequent sore throats. Examination discloses no edema of the face or extremities. The tonsils are large and infected. There is an apparent loss of weight. The urine is loaded with albumin; there are no casts or sugar. The blood nonprotein nitrogen is 33½ mg per hundred cubic centimeters. The blood Kahn reaction is 4 plus. The patient's general condition is fair, her appetite good. There are no reflex changes. Should she have antisyphilitic therapy if so what should be used and how? What should be the best method of treating the renal condition? Is it safe to do a tonsillectomy? Is it safe to coagulate the tonsils with a high frequency coagulator?

M D Massachusetts

ANSWER—If the miscarriage occurred in the early months of pregnancy, it most likely was not caused by syphilis. If it took place in the later months it may have been due to the syphilitic infection. No specific information is given as to why both tubes and one ovary were removed. Surely syphilis is not an indication for such an operation. The hot flashes and perspiration may be endocrinal in origin, based on the assumption that the remaining ovary for some reason or other has ceased to function. The albuminuria and edema of the hands, legs and face are due in all likelihood to an impairment in renal function. This in turn may have resulted from intensive antisyphilitic treatment or it may have resulted from a focus of infection such as the diseased tonsils, which the patient is presumed to have.

More antisyphilitic therapy should be given but because of the renal disturbance great caution must be exercised. Small doses of the heavy metals should be used, but the urine should be carefully controlled for the amount of albumin present, for casts and for the amount of nonprotein nitrogen it contains. The ocular fundi should also be examined from time to time. It is advisable to administer 1 cc of bismuth subchloride intramuscularly once a week for four or six doses. This should be followed by four or six injections of 0.3 Gm of neoarsphenamine given intramuscularly once a week. If any abnormal urinary signs appear this treatment should be stopped. Potassium iodide should be administered by mouth in addition to the use of the heavy metals. Mercuric benzoate may be added to the treatment.

It is a good plan to remove the tonsils in the hope that they may be the source of the kidney damage. Electric coagulation will most likely not give as satisfactory a result as

operative removal of the tonsils, which may readily be performed under local anesthesia

There is no specific way of treating the renal condition other than by treating or removing the cause, which in this case may be syphilis, antisyphilitic treatment or tonsillitis

HABITUAL ABORTION

To the Editor—I should like to consult you regarding the management of an obstetric case. A woman aged 34 is three and one-half months pregnant. She has never carried a child to viability but twice previously she has had a spontaneous miscarriage, once at six months in 1922 and once at five and a half months in 1929. So far as I can determine the woman is perfectly healthy except for a nervous indigestion and irritable colon of years standing. The gastrointestinal symptoms are now and have been with her other pregnancies rather less marked than they are when she is not pregnant. The diagnosis of the gastrointestinal condition has been made after careful clinical and roentgen studies by an internist of high standing. The urine and blood pressure are normal and always have been. The blood Wassermann reaction is negative. Pelvic measurements are normal. There is a slight endocervicitis but probably no more than a majority of women have. The fetus and placenta that miscarried in 1929 looked perfectly normal so far as I could see. I am giving the patient 1 cc of antuitrin S hypodermically every three days and restricting her activity. She feels quite well at present. However I will say that in 1929 she felt perfectly well until the day she suddenly went into labor and miscarried. How would you handle this case from now on? Would you put her to bed after quickening? She would do almost anything to insure a living child.

M D Iowa

ANSWER—The question of habitual abortion has been answered on numerous occasions in these columns, and little has been added to our knowledge in recent years. If syphilis, tuberculosis, focal infections, hematopathias and avitaminosis can be excluded, and if there is no malformation of the uterus, particularly infantilism and chronic infections, one has to proceed on general grounds, and the question of endocrines comes up. Of late a disturbance of the balance between estrogenic hormones and corpus luteum hormones has been considered as a frequent cause of habitual abortion, and progesterin, which is the corpus luteum hormone, is being administered as a prophylactic. Lack of thyroid is likewise a cause and one might administer it if the basal metabolism rate is below normal or even just normal.

Rest in bed with the foot of the bed elevated from 6 to 8 inches should be insisted on for the full time of pregnancy. This is a hard sentence but deserves carrying out. The diet should of course be rich in vitamins, and calcium also is usually given.

SENSITIZATION TO RUBBER

To the Editor—I am seeking information regarding a dermatitis produced by surgeons' gloves. For the last year and a half I have been the victim of a distressing condition of my hands and they became so inflamed in January that I was told to quit work for a while. February 1 I boarded a slow going ship and remained at sea for six months during which time my hands completely healed. I returned and resumed work on August 1 and I carefully avoided all possible irritating substances as much as possible. I assisted in an appendix operation and in less than six hours my hands were red and the skin was swollen and there was marked itching and burning. They showed evidence of improving in a couple of days. From the first to the twelfth I assisted in four operations and on each occasion a similar reaction occurred. It was more violent on each following occasion. The reaction stops where the glove meets the cuff of the gown. The operator and I felt that it was from contact obtained from and in the operating room. We tested the skin on my forearm to a section of a sterile rubber glove to the talcum with rubber from the glove over it and also to the talcum alone. We left it in contact for one hour. The skin from four to six hours later was very irritated where rubber alone was used mildly irritated where the talcum and rubber was used and gave no reaction where the talcum alone was used. Any information you can pass to me about this condition will be much appreciated as it is very distressing to me.

M D Texas

ANSWER—From the history and the result of the patch tests, this is a case of sensitization to rubber. Such cases of sensitization are due to accelerators used in the process of the manufacturing of rubber. Among the accelerators used, hexamethylenetetramine (methenamine) is the one most irritating to the skin. An outbreak of dermatitis among the linemen wearing rubber gloves in which tetramethylthiuram disulfide was used as an accelerator was proved to have been due to hypersensitivity to this substance (Osborne E D, and Putnam E D. *Industrial Dermatoses* THE JOURNAL, Sept 17, 1932, p 972). Many of the accelerators or antioxidants may come out of the cured rubber in the form of bloom if the curing is not properly done or if too great an amount is mixed with the rubber. Such bloom may cause dermatitis.

Most of the accelerators and antioxidants used are harmless to normal skin, but hypersensitivity may occur toward any of them (Skin Hazards in American Industry, Pub Health Bull 215, October 1934).

Patch testing with rubber gloves from different manufacturers will probably reveal a type that can be used without irritation.

PSYCHIC FRIGIDITY

To the Editor—A woman aged 27, married two years fails to reach a climax in her sexual relations. Occasionally she does attain this climax, but it seems to do her more harm than good as it causes her to be the more resentful when she does not. Neither local nor general physical examination reveals any anatomic reason for her difficulty. Her marital relations are normally conducted and her husband does all in his power to help her obtain sexual gratification. There is no frigidity per se, no dyspareunia, no dislike for the sexual act. Her menstrual periods are normal and regular. She is in good health. The husband is 27 years of age and in good physical condition (I have examined him also). His part of their marital relations seems to be normal as to both manner and result. He is quite concerned about his wife's inability to obtain as much satisfaction as he does from their marital activities. The only method of birth control used is abstinence during the fertile period. The problem may not appear to be serious but nevertheless it has created in this woman a feeling of being cheated and this in turn is the source of an unpleasant undercurrent in an otherwise happy married life. In my instructions to this couple along with a discussion of the anatomy and physiology of the female genitals I made a suggestion that she read erotic literature on occasion. This worked like a charm for a while but now that the reading is a duty it has lost its effectiveness. What course of treatment would you suggest here? Is there any endocrine treatment that might be of use? Please omit name and address.

M D Illinois

ANSWER—The patient apparently has a frigidity of psychic origin. There is probably no physical basis for it, and the administration of organ extracts would not be effective. The patient needs a careful psychiatric investigation in order to determine the basis for her frigidity. It is only by understanding its cause that treatment can be instituted by appropriate psychotherapy.

DINITROPHENOL AND METABOLISM

To the Editor—Kindly inform me whether the use of dinitrophenol can account for a continued high metabolic rate several months after the drug has been discontinued.

RALPH FALK M D Boise Idaho

ANSWER—The peak of the effect of a single dose of dinitrophenol is reached in about six hours and there is complete return to the previous metabolic rate in from two to three days. When dinitrophenol has been given for prolonged periods there is no cumulation of the drug in the body, since the rates of excretion or detoxification soon get in equilibrium with the rate of intake. When the medication is stopped, the drug is practically all excreted within a few days, and the metabolism as promptly returns to its normal level. Therefore there is no basis for suspecting that a metabolism which remains elevated for several months after the use of dinitrophenol has been discontinued is due to the persistent action of the drug. It would seem desirable to make a thorough search for other causes of increased metabolism.

SUPERFECUNDATION—TWINS BY DIFFERENT FATHERS

To the Editor—Please inform me if there is an authentic record of twins by different fathers.

FRANK P NORMAN M D Columbus G

ANSWER—In his book "Life in the Making," A F Gutt macher records two cases of superfecundation, which means the fertilization of two ova within a short period by spermatozoa from separate copulations. Most authorities agree that superfecundation is possible and also that it actually occurs. The two instances recorded concern women giving birth simultaneously to a white and a black child in which there seemed to have been adequate records of intercourse within comparatively short periods with black and white males.

EPHEDRINE AND THE LIVER—EFFECTS OF ALCOHOL ON INSULIN

To the Editor—1 Does ephedrine in any way have a tendency to demobilize the glycogen from the liver as is the case with epinephrine? 2 Does alcohol need to be considered in the dosage of insulin for patients with diabetes when the administration of insulin is necessary?

F J HIRSCHBOECK M D Duluth Minn

ANSWER—1 In very large doses, ephedrine occasionally produces hyperglycemia, but the glycogenolytic action is so weak that glycosuria does not occur.

2 No.

Book Notices

Diseases of the Liver Gall Bladder Ducts and Pancreas Their Diagnosis and Treatment By Samuel Weiss MD FACP Clinical Professor of Gastroenterology N Y Polyclinic Medical School and Hospital Chapter on Surgery by J Prescott Grant MD FACS MRCs Professor of Surgery N Y Polyclinic Medical School and Hospital Chapter on Roentgenology by A Judson Quimby MD FACP Professor of Roentgenology N Y Polyclinic Medical School and Hospital Cloth Price \$10 Pp 1 099 with 364 illustrations New York Paul B Hoeber Inc 1935

This volume consists of 931 pages of reading material and nearly 100 pages of references, of which less than one third are quoted in the text. The latter simply contribute to the bulkiness of the book that is already big. What one looks for in a book by a single author is not simply an accumulation of everything ever mentioned by various writers but a systematic, analytic and evaluated statement of facts in which two things should stand out: a clear cut clinical picture of the disease under discussion from which one can benefit by the author's experience and an evaluation of the work of others in such a way that the reader can obtain a definite opinion of what is important and what is not. The reviewer, who spent considerable time and effort in examining this book, was desirous of being fair and sought information. The author undoubtedly spent an enormous amount of time and energy in getting out this large compilation, which is encyclopedic in character, but he has failed to inject that personal touch which causes a book to stand out from the multitude. Quotations from as yet unaccepted work are given undue prominence. The section on clinical and experimental physiology is quite large but frequently fails to state prevailing opinions. Some extravagant therapeutic claims for the pancreatic hormones are made here. Considerable space is devoted to a discussion of the tests of liver function, but the reader is at loss to know which ones are preferable. It would be interesting to know how hippuric acid finds its way in duodenal contents obtained by biliary drainage. It is not clear why furred tongue, heartburn and hematemesis with various cardiac, renal, neurologic and dermatologic manifestations are referred to as functional. It is generally accepted that the tests for liver dysfunction have their real value in fairly advanced hepatic disease. Still the author states that the newer tests of liver function are of value in the diagnosis of early mild hepatic insufficiency. It should be emphasized that in well developed acute yellow atrophy sugar is made available far better by venoclysis or hypodermoclysis than by proctoclysis. The Hanot-Gilbert and the Hanot biliary cirrhosis are described as different diseases but are not separated in the charts of differential diagnosis. The chapters on cholecystitis and cholelithiasis are probably the best but still are lacking in what has already been mentioned. The chapter on the medical treatment of gallstones is a veritable hodgepodge. The author gives space to listing a multitude of remedies and measures for the condition, as though medically curable. High enemas and low enemas, calomel and intestinal antiferments seem to have their indications. Cholecystitis, it appears, may be prevented by biliary disinfectants, such as methenamine, salicylates and ammonium chloride in 7½ grain (0.5 Gm) doses. Hyperchlorhydria must be avoided, it is said, because it leads to gallstone formation. Saline laxatives, especially sodium phosphate, bismuth subnitrate and sodium bicarbonate before meals and a proper diet in the presence of inflammatory catarrhal conditions of the duodenum and stomach it is intimated will prevent the infection of the biliary tract and the formation of gallstones. The author quotes the ridiculous report of the cure of carcinoma of the gallbladder and the passage of fifty-two calculi by the use of olive oil. Solution of posterior pituitary, chloretics, chologogues, salines and various herbs in shotgun prescriptions are mentioned as remedies for gallstones. Biliary drainage finds an ardent supporter in the treatment of cirrhosis, dermatoses, arthritis of biliary origin and cystic duct obstruction on a catharrhal basis. The chapters on pancreatic disease are not as complete as the rest of the book. Those on surgical treatment by J Prescott Grant and on roentgenology by Judson Quimby are satisfactory. There are many excellent illustrations, charts and diagrams.

Les astereognosies. Pathologie du toucher. Clinique physiologique topographique. Par J P L Delay. Preface du Pr Guillaum. Paper. Price 65 francs. Pp 524 with 19 illustrations. Paris: Masson & Cie 1935.

This book discusses in detail the pathology of loss of ability to appreciate objects or things by means of feeling or touching (astereognosis). All the work was done in the neurologic clinic of Salpêtrière under the supervision of George Guillaum and in the laboratory of physiology of sensations in the College of France under the supervision of H Pieron. Delay includes three syndromes in his study of astereognosis. They are (1) l'amorphognosie, (2) l'ahylognosie and (3) l'asymbolic tactile. L'amorphognosie is a term given to that condition in which there is an inability to appreciate the form, length and spatial qualities of an object. L'ahylognosie refers to inability to appreciate the density, thermic conductivity, rugosity and molecular qualities of an object. The asymbolic tactile is the inability to appreciate the species or use of an object. The book is divided into six parts. The first part is further subdivided into three chapters. They are definition and classification of astereognosis, the two classic conceptions of astereognosis and the analysis of touch. The second part is subdivided into definition of elementary sensations, method of examination of elementary sensations and the anesthetics and sensory abnormalities. The third part consists of three chapters on the ahynognosias and the difficulties of detailed analysis. The fourth part discusses in three chapters the amorphognosias and the difficulties of spatial analysis. The fifth part is subdivided into three chapters and discusses the tactile asymbolia and semantic agnosias. The sixth part is made up of nine chapters and discusses special studies of astereognosis in detail. This book is highly recommended for use to all neuropsychiatrists and students interested in cortical and spinal as well as peripheral abnormalities of sensation related to stereognostic function. There is a detailed bibliography consisting of thirty-nine printed pages.

The Medical Man and the Witch During the Renaissance. By Gregory Zilboorg MD. The Hideyo Noguchi Lectures. Publications of the Institute of the History of Medicine. The Johns Hopkins University. Third Series. Volume II. Cloth. Price \$2.50. Pp 215 with illustrations. Baltimore: Johns Hopkins Press 1935.

The author is a student of Bekhterev, graduate of the psychoneurologic institute of Petrograd, psychiatrist at Bloomingdale Hospital, and a specialist in the field of the history of medical psychology.

The psychiatrist is of necessity deeply concerned with the cultural background and genetic origins of his patient. The general tendency among this class of medical specialists to be more interested in the historical bases of medicine than are physicians devoted to other specialties thus seems to have a psychologic origin. Psychiatry, more than any other field of development in modern medicine, must understand the mental atmosphere environing the patient, but the knowledge of today cannot be utilized as a guide to the problems of the mentally sick as they confronted the physician of earlier days, especially of days when astrology, magic and witchcraft polluted the social atmosphere. Dr Zilboorg's investigations enable us to comprehend more fully the bedevilment which afflicted states and communities, the bases for the mass psychoses, the legally authorized tortures and cruel burnings of deranged women and frightened children. Most of all, they clearly set forth the significance of the writings of Weyer, who, as physician, sought by direct observation and intensive study of mental cases, which were sometimes brought into his own home for more intimate observation, to develop an objective point of view of mental aberrancy and to establish the obligation of the physician to care for such cases and the rights of the accused person to have medical care rather than the judicial consignment to the torture chamber and stake. The work of Weyer is the more remarkable, as it flew directly in the face of custom and was without benefit of a Kraepelin or a Freud.

The three chapters deal respectively with (1) the physiologic and psychologic aspects of the Malleus Maleficarum (The Witch's Hammer), (2) medicine and the witch in the sixteenth century and (3), Johann Weyer, the founder of modern psychiatry.

The Witch's Hammer (about 1487-1489) was the work of two Dominican monks, Johann Sprenger and Heinrich Kramer,

appointed by Pope Innocent VIII in 1484 to uncover, apprehend and try witches and wizards in the Rhine provinces and in northern Germany. This volume became the textbook of the Inquisition. It was printed ten times before 1669 and ran through ten editions in the following century. This book, a heavy volume in quarto, has been characterized as "so insane, so raw and cruel, and it leads to such terrible conclusions, that never before or since did such a unified combination of horrible characteristics flow from a human pen."

The second part presents a series of "case histories" with a view of showing how little, or much, the physician played a part in the tragedies typical of these times. This is truly an exceedingly difficult task, largely obscured by extraneous affairs and best illustrated in only a relatively few instances in medical literature of the day.

The concluding part analyzes the writings of Johann Weyer (1515-1588), a student of Cornelius Agrippa in Bonn, and thus in the tradition of Paracelsus and Erasmus, with a degree in medicine from Paris, city physician at Arnheim and personal physician throughout his later life to the enlightened and liberal Duke Wilhelm of Julich-Cleve-Berg. Weyer looked on the demoniacal world about him as an enormous clinic teeming with sick people, he made clinical analyses of cases, ransacked the literature of the field, called on the encowled ignorant monks to leave the management of witches and the bewitched to physicians, and to reduce expenses by putting logs and faggots to a better use than in attempting to destroy errors by destroying human beings. He protested that witchcraft was a delusion, that witches could do no harm to men or animals, and that "no one can more correctly judge these things than we physicians, whose ears and hearts are being constantly tortured by this superstition."

Weyer's scientific ability is also demonstrated in his lucid account of what appears to have been trichinosis, of English sweating sickness, of syphilis, of "pestilential cough" (influenzal pneumonia), of erysipelas and of scurvy. With psychologic perspicacity he unraveled the clinical history of these bewitched persons in whose bodies devils had deposited various and odd foreign bodies. He investigated and applied surgical aid to atresias of the new-born and to the relief of suppressed menstruation. He denounced superstition as heathenism and scathingly attacked quackery and nonmedical methods of magic and exorcism, exposed malingerers, and, although his writings show clearly that he had not arrived at a disbelief in the devil, he devoted his life to banishing him and all his works from their enormous, appalling and malevolent action in human affairs.

An indirect consequence of the recognition of the psychiatric factor in disease, initiated by Weyer, has been that the medical profession has displaced the devil (perhaps in some individual instances replaced him) and has thereby progressively risen to ever higher levels of opportunity, power and responsibility in human affairs.

The Epidemiology of Pneumonia on the Witwatersrand Goldfields and the Prevention of Pneumonia and Other Allied Acute Respiratory Diseases in Native Labourers in South Africa by Means of Vaccine. By Sir Spencer Hister LL.D. MRCS. LRCP. Director of the Institute and David Ordman B.A. MB ChB. Department of Bacteriology. The South African Institute for Medical Research. With the following relative papers: (1) Prophylactic Inoculation Against Pneumonia and Other Acute Respiratory Diseases with Vaccine on the Randfontein Estates Mine. By P. A. Peall MB MRCS LRCP. Senior Medical Officer. Randfontein Estates Gold Mining Co. Ltd. (2) Pneumonia in the Native Mine Labourers of the Northern Rhodesia Copperfields with an account of an Experiment in Pneumonia Prophylaxis by Means of a Vaccine on the Roan Antelope Mine. By D. Ordman B.A. MB ChB. Department of Bacteriology. The South African Institute for Medical Research. Publications of the South African Institute for Medical Research No. XXXIII (Vol. VII) Paper. Pp. 124 with 21 illustrations. Johannesburg. South African Institute for Medical Research 1935.

A twenty four year study is reported on the prophylaxis of pneumonia among miners in South Africa with autogenous vaccine. The population at any one time totaled about 200 000 natives from various sections of South Africa exclusive (after 1918) of those from north of latitude 22° S as a result of their high degree of susceptibility to respiratory infections. The men worked through periods of from six months to a year, and no follow up study of their health after leaving the mines is

reported. Studies were made of housing and sanitary conditions in the mines and in the barracks, and also of the diet of the miners. Any changes made apparently had little effect on respiratory infections. No information is given as to the age of the individuals studied.

The investigation is divided into three periods: first, 1911-1913, a review of Wright's work with mixed pneumococcus vaccine; second, 1913-1925, in which the vaccine used continued for the most part freshly isolated pneumococci of the groups as classified by Lister; and third, 1926-1934, in which the vaccine was modified because the respiratory infection was observed to change from a pneumococcal pneumonia to a mixed infection due largely to the streptococcus, the staphylococcus and Friedlander's bacillus.

A lower incidence and mortality rate among the inoculated men as compared to the noninoculated in the second period was explained by the use of three injections of mixed types of pneumococcus vaccine. But in 1926, even though this vaccine was used, a rise in incidence and mortality rate led to a study of the causative agent. On discovery of a change in the bacterial flora to the streptococcus, the staphylococcus and Friedlander's bacillus instead of various types of pneumococci, a fresh autogenous vaccine was made from these strains along with type B pneumococcus (American type II). This vaccine was injected in men in some of the so called bad mines, and men in other "bad mines" were considered controls. During 1930-1933 a reduction of more than 50 per cent occurred in both incidence and mortality among the inoculated group as compared to the noninoculated. Although injections were made in small numbers of men, the authors stated that this reduction was significant as compared to the incidence and mortality in the entire mine area.

The study is of special interest because of the observation of the change in bacterial flora from a pneumococcus prevalence to a pneumococcus absence in respiratory infections. Following injection of autogenous pneumococcus vaccine there was a reduction in the incidence and mortality of pneumococcal lobar pneumonia, and following injection of autogenous vaccine containing the prevalent organisms other than pneumococci there was also a decrease in the incidence and mortality rate due to respiratory diseases. The authors assume that a virus is the etiologic agent of the respiratory diseases and that the organisms isolated were possibly secondary invaders. No proof of this supposition is given.

Woman. An Historical Gynaecological and Anthropological Compendium. By Hermann Heinrich Ploss, Max Bartels and Paul Bartels. Edited by Eric John Dingwall. In three volumes. Cloth. Price £8 8s per set. Pp. 655, 822, 543 with 1 009 illustrations. London. William Heinemann Ltd. 1935.

The first edition of Ploss and Bartels' notable work appeared in Germany in 1885, the second was published in 1887, and the ninth edition appeared in 1908. In 1927 an eleventh edition was issued in which much supplementary material and photographs were added. Thus the book becomes a well established source book of information on the anthropology, gynecology and ethnology of women.

In the present edition E. J. Dingwall has slightly modified the text in the interest of new evidence and has introduced new material. More space is devoted to anatomy, to crime and to the social sciences than was given in any of the German editions. In preparing this text the author has had the assistance of many competent British scholars.

The book is developed now in three volumes. The first volume discusses the anthropology, psychology and anatomy of the female as they are distinguished from the male. The second part of the first volume concerns the social status and position of woman in civilization from the earliest times, and then the girl from birth to the time of puberty. Here are given the superstitions and religious beliefs associated with menstruation.

The second volume deals primarily with the process of birth, beginning with the sex relationships, discussing love, courtship and marriage, sterility and fertility, pregnancy, the hygiene of pregnancy, abortion, processes of childbirth and superstitions. There are excellent chapters on the history of obstetrics, its practice among various foreign peoples and finally the care of the afterbirth.

The final volume continues with discussions of labor and the puerperium, cesarean section and lactation. Here are special sections on the beliefs associated with the development and care of the breasts. Other chapters concern the old maid, woman as a saint, the widow, the menopause, old age, and death.

The book is handsomely printed on fine enameled stock. It is profusely illustrated with thousands of pictures (some in colors) and there is a tremendous bibliography.

Stop Light. By William Louis Potrat, Professor of Biology, Wake Forest College, Wake Forest, N. C. Cloth. Price 75 cents. Pp. 91. Nashville: Broadman Press, 1935.

This is not temperance education, though it pays lip service to the principle of education as opposed to propaganda. It is propaganda for national prohibition, not education in the effect of alcohol on the health of the user. "I seek," says the author, "to arrest attention and direct it upon the elementary and undisputed facts of beverage alcohol as they are presented in the cold science of the time." In another place, "we seek the fact, the truth, no fancy, no theory, no extravagance of fanaticism, no interested perversion of the propagandist, will be allowed a hearing." Having thus vehemently castigated the propagandist, the author proceeds to write four chapters of pure propaganda, which would have been better and more worthy of respect as propaganda if it had been presented frankly for what it is, since obviously the author, or any one else, has a right to crusade for prohibition by legislative fiat if he has not learned that such a procedure is psychologically unsound. The reviewer holds no brief for or against prohibition, as long as the rights of the physician to decide as to the merits of alcohol as a therapeutic agent are not curtailed. He does hold, however, that propaganda is not the same as education. The author's chapter on the history of alcohol contains a few citations from ancient literature and much material laudatory of more or less modern organizations devoted to prohibition. The chapter on physiology, besides being incomplete as compared with other recent popular works on alcohol, is definitely colored to emphasize the views of the writer and to minimize opposing opinions. This book is a good choice to recommend for the reading of those whose minds are already made up in favor of national prohibition by law, and who want the comfort of confirmation. The skeptic or the opponent of the author's views will hardly be convinced by the evidence presented or the manner of its presentation. The seeker for facts "in the cold science of the time" will find better choices in other recent popular books on alcohol.

Report of the Sixth Australian Cancer Conference Held at Canberra 13th-17th May 1935. Commonwealth of Australia. Paper. Pp. 54 with 8 illustrations. Canberra: L. F. Johnston, 1935.

The sixth Australian cancer conference was convened by the director general of health, Commonwealth Department of Health, and met in Canberra from Monday to Friday, May 13-17, 1935. The conference, after a full morning's discussion of the many aspects, passed resolutions adopting Dr. Holmes's review and recommending the formation of a national organization along the lines indicated in that review and the appointment of liaison officers in the commonwealth and states. It was decided that the next meeting of the Australian cancer conference should be held in Melbourne but that every second year the conference should be held in Canberra. The arrangements for the next conference was left in the hands of the commonwealth department of health in consultation with the Royal Australian College of Surgeons, and an agenda committee was selected. The conference also passed a resolution supporting the proposal for the early establishment of a Medical Research Council.

In order to pave the way for more complete understanding and effective cooperation on the part of general practitioners in the developments for the control of cancer, the conference recommended that the universities should introduce into the medical curriculum some instruction in radiotherapeutics. The subject of roentgen therapy received a large amount of attention of the conference. The question of physical investigation into the problems of the radiotherapists and of assistance to radiotherapists in overcoming their difficulties in relation to the determination of the quality of x-rays used in treatment, the dosage administered at varying depths in the tissues, and other aspects has received much attention during the year.

There follows a review of research carried out by the Cancer Research Committee of the University of Sydney during 1934. Dr. Sande's report to the federal government of Australia is presented in three parts: publicity, treatment and research. After an excellent review of the cancer problem as observed in various American and European centers, he concludes with the following recommendations:

To secure improved cooperation between the states I suggest that the government should give serious consideration to the establishment of an Australian cancer commission as an independent body with statutory endowment to deal with the three main aspects of cancer work: firstly cancer publicity, secondly cancer treatment and thirdly cancer research. One of the commissioners should be a publicist, another a therapist and the third a scientist. These men should be in the active period of life with vision, driving power and experience of the different aspects of the work. They might be between 35 and 45 years of age and if they prove themselves, might be expected to hold office for ten or fifteen years. They may need consultant or departmental assistance but I think they should be independent of any existing organization and responsible only to the minister or to parliament.

The report is comprehensive and well presented. It should be read by all those who are interested in problems of organization as related to cancer control.

Die Haut und Geschlechtskrankheiten. Eine zusammenfassende Darstellung für die Praxis. Herausgegeben von Prof. Dr. Leopold Arzt und Prof. Dr. Karl Zieler. Lieferung 25. Band I. Verhütung und Bekämpfung der Geschlechtskrankheiten. Von Prof. Dr. Julius K. Mayer. Nichtvenereische Krankheiten der Geschlechtsorgane. Balanitis, Phimose und Paraphimose. Von Prof. Dr. W. Frei. Die nichtgonorrhoeische Harnröhrenentzündung. Von Prof. Dr. Gustav Scherber. Induratio penis plastica. Von Prof. Dr. Gustav Scherber. Ulcus vulvae acutum (Ulcus pseudoluberculorum, Scheldenbazillengeschwüre). Von Prof. Dr. Gustav Scherber. Alute Gangrän der aussere Geschlechtsorgane. Von Prof. Dr. Gustav Scherber. Titel und Inhaltsverzeichnis zu Band I. Paper. Price 9.40 marks. Pp. 525, 690 with 85 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1935.

Die Haut und Geschlechtskrankheiten. Eine zusammenfassende Darstellung für die Praxis. Herausgegeben von Prof. Dr. Leopold Arzt und Prof. Dr. Karl Zieler. Lieferung 26/27. Band II. Die bösartigen Geschwülste der Haut. Von Prof. Dr. Leo Kumer und Prof. Dr. Franz Josef Lang. Gutartige Neubildungen der Haut. Von Prof. Dr. Leopold Arzt und Prof. Dr. Herbert Fuhs. Fragliche Neubildungen und nahestehende Krankheiten. Von Prof. Dr. Alfred Stühmer. Titel und Inhaltsverzeichnis zu Band II. Gesamt Sachverzeichnis. Paper. Price 28.50 marks. Pp. 829, 1192 with 297 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1935.

The final instalments (25, 26 and 27) of this comprehensive work deserve additional laudatory comment. In the section on nonvenereal diseases of the generative organs is a valuable contribution by Professor Frei on the different forms of balanitis and another one by Professor Schreiber on ulcus vulvae acutum. The chapter on malignant tumors by Kumer and Lang occupies 145 pages and that by Arzt and Fuhs on benign tumors of the skin 190 pages. The colored and black and white illustrations of clinical cases are unusually numerous and well selected and there are many excellent reproductions of photomicrographs. The completion of this masterly work together with a comprehensive index should be a source of gratification to the editors and publishers alike and will be welcomed by students of dermatology.

The Parathyroids in Health and in Disease. By David H. Shelling. B.Sc. M.D. Cloth. Price \$6. Pp. 335 with 26 illustrations. St. Louis: C. V. Mosby Company, 1935.

This is an excellent discussion of a subject of far wider scope than the title indicates. Each chapter carries its own bibliography of well selected references, not necessarily complete but comprehensive and representative. One wonders just why the pathology of the parathyroids was discussed before the physiology. The contents of the first four chapters, embracing the history, the anatomy, the pathology and the physiology of the parathyroids, constitute conservative discussions with, however, little that is not found in other recent reviews, except that the author has enlivened the material sufficiently to bring it out of the class of a dry review. The discussion of the parathyroid hormone is brief, concise and well supported by experimental evidence, considerable space is devoted to bioassay. In the next two chapters there is a wealth of material on the clinical physiology particularly that relating to bony tissues and to the reticulo endothelial system, much of which has never before appeared in any review. There is one short chapter on

the relations of the parathyroids to other endocrine glands, all based on well authenticated experimental results, there is a short chapter on the relation of vitamin D to parathyroid function, devoted mainly to an alignment of evidence for and against the theory that the vitamin acts through the parathyroids. This is the high light of the book, since a logical reconciliation of the facts is brought about in a masterful manner and the reader closes the chapter with a feeling of satisfaction. The final chapter is devoted to a timely discussion of the therapeutics of the parathyroid hormone, from which the reader obtains a clear notion of the contraindications. Some of the illustrative charts are too complex for the general reader to interpret. The anatomic and microscopic illustrations are apparently original or reproductions of originals in previously published work of the author or his associates. Despite the many points of excellence, the price seems rather out of proportion when the book is compared with monographs of similar scope on other subjects. Nevertheless the timeliness of subject matter and the general excellence of presentation should recommend it both to the physician and to the investigator.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Expert Testimony Right of Attorney to Obligate Client to Pay Fee of Expert Witness—The defendant in this case had been injured in an accident. The physician-plaintiff, a roentgenologist, interpreted certain roentgenograms for her attending physician and was paid for doing so. Subsequently she sued the corporation that she held responsible for her injuries, and her attorney requested the physician-plaintiff to testify on her behalf as an expert witness in that suit. The defendant herself did not expressly employ the physician-plaintiff, but she was present at the trial in the course of his testimony and, without objection on her part, listened to it. She refused to pay for the services thus rendered, however, and the physician-plaintiff sued to recover their value. The defendant did not deny the necessity for his testimony as an expert witness or the reasonableness of his fee, but she denied that she had employed him or that her counsel had authority to employ him on her behalf. On motion of the defendant, the trial court withdrew the case from the consideration of the jury, on the ground that the evidence did not support the plaintiff's claim. The physician-plaintiff thereupon appealed to the supreme court of New Jersey.

An attorney, said the supreme court, has no authority under his retainer to surrender or waive without the consent of his client any substantial legal right. But when the defendant's attorney obligated his client to the extent of \$100, he did not surrender or waive any of his client's substantial rights. His act was that of a careful and prudent attorney, to protect and promote his client's interest. It is common knowledge, said the court that, when one has sustained serious injuries, roentgenograms are frequently made by experts to determine the nature and extent of such injuries, that an expert is necessary to interpret such roentgenograms and that it is common practice to use the testimony of such experts whenever available, in a suit to recover damages for such injuries. Furthermore, continued the court if the propriety of a challenged expenditure for which the defendant denied liability is to be judged by the result obtained the defendant's failure to challenge either the necessity of the expert testimony given or the reasonableness of the fee charged is readily understood, in the case in which such testimony was given the defendant in this case who was the plaintiff there, recovered a verdict of \$15,000.

It is far from a mere conjecture said the supreme court that if the attorney had failed to produce this expert testimony—and he could not produce it unless it was volunteered without arranging for the payment of the expert—he might well have subjected himself to a claim of negligence, at the suit of his client. The supreme court was of the opinion therefore,

that an attorney who is retained to prosecute a suit for damages arising out of an accident has implied authority to obligate his client to pay the fee of an expert witness whom he employs to testify in behalf of such client, when the necessity for such a witness and the reasonableness of his fee are not challenged. Accordingly the supreme court reversed the judgment of the trial court withdrawing the case from the jury.—*Klein v. Boylan (N J)*, 179 A 638.

Malpractice Joint Liability of Physicians—The defendant Canfield, with the assistance of defendant Van Ark, treated the plaintiff's fractured leg. The plaintiff, alleging negligence, sued both physicians. The jury returned a verdict for the plaintiff, "\$4,000 on Mr [Dr] Wilson Canfield and \$2,000 on Bert Van Ark." The trial court rejected this verdict and directed the jury to retire again to the jury room, after instructing them as follows:

You will retire to your jury room for reconsideration of your verdict. If you find both of these defendants guilty of negligence you will return a verdict in one sum against both defendants for the total amount of plaintiff's damages.

The jury then returned a verdict for \$6,000 against both defendants. Dr Van Ark appealed to the Supreme Court of Michigan.

Each defendant, said the Supreme Court, while serving with the other is answerable for his own conduct and also for the conduct of the other which he either observed or in the exercise of reasonable diligence should have observed, for their joint acts of commission or omission both defendants are liable. An act done by one, however, in the absence of the other, unless done by agreement between them, cannot be attributed to the defendant who did not participate in it. Lack of skill or care on the part of Dr Canfield, in the absence of Dr Van Ark, cannot be charged against the latter. The jury, continued the court, by its first verdict, awarding damages amounting to \$4,000 against Dr Canfield and \$2,000 against Dr Van Ark, evidently found Dr Canfield guilty of malpractice, not only jointly with Dr Van Ark, but also separately from him. For the joint malpractice a single-sum verdict could be returned, for the malpractice of Dr Canfield alone, no such verdict was permissible. The judgment entered on the second verdict was manifestly erroneous as to Dr Van Ark. It failed to distinguish between the joint liability of the defendants and the liability of each of them separately, and it held Dr Van Ark liable to respond in damages for malpractice of Dr Canfield in which Dr Van Ark was not a participant.

The court reversed the judgment against Dr Van Ark and ordered a new trial.—*Rodgers v. Canfield (Mich)*, 262 N W 409.

Pharmacy Practice Acts Validity of Provisions Limiting Registration to U S Citizens—The California pharmacy practice act (St 1905, p 536, sections 2 and 3, as amended St, 1933, p 2192) forbids the registration of persons who are not "citizens of the United States." Accordingly, the California state board of pharmacy refused to examine Sashihara and certain other applicants who came within this prohibition. The rejected applicants thereupon petitioned for a writ of mandamus to compel the board to examine them. The trial court entered a judgment for the board, and the plaintiffs appealed to the district court of appeal second district, division 2, California.

The plaintiffs contended that the provisions of the pharmacy practice act referred to were invalid because in conflict with a treaty entered into between the United States and the nation of which they were subjects, which permitted citizens or subjects of each of the high contracting parties to carry on trade, to own shops and generally to do anything incident to or necessary for trade on the same terms as native citizens or subjects. The matter the district court of appeal answered resolves itself into the question Is the occupation of being a pharmacist a trade or a profession? If it is a trade the treaty is violated, if it is a profession, the treaty is not violated. In this connection it is necessary to keep in mind the distinction between the business or trade of a druggist as the owner or operator of a drug store, and the practice of pharmacy as such. A pharmacist compounds prescriptions and in so doing he is exercising his knowledge of the science of pharmacy but who-

ever sells the compounded prescription to a customer, in so doing, acts as a clerk or as a merchant. The statute under discussion does not prevent aliens from operating or owning drug stores or working as clerks therein, it merely prohibits them from being registered as pharmacists and from compounding prescriptions. The court was satisfied that the practice of pharmacy is a profession and that therefore the pharmacy practice act was not in violation of the treaty referred to.

The plaintiff next contended that the requirements under discussion constituted an abuse of the police power, created an arbitrary and discriminatory classification, and denied to aliens the equal protection of the laws. We are satisfied, said the district court of appeal, that the object sought to be accomplished by the legislation in question is the protection of the public health, safety, and general welfare, and that there is a reasonable relation between that object and the means adopted. This court cannot say that the classification excluding aliens is palpably arbitrary. In the practice of pharmacy, chemicals and poisons are constantly used and compounded. If not handled with great caution, much harm might be inflicted. And it is obvious from these facts and others that there may be a reasonable basis for the existence of the discrimination against aliens and therefore that the act under discussion is not an abuse of the police power. The pharmacy practice act, accordingly, the court held, did not deny aliens the equal protection of the laws.

The court accordingly affirmed the judgment of the lower court, dismissing the petition for a writ of mandamus—*Sashihara v State Board of Pharmacy (Calif)*, 46 P (2d) 804.

Accident Insurance Death from Degeneration of Liver Attributed to Trauma—The plaintiff was the beneficiary under two life insurance policies issued to her husband by the defendant insurance company. Each policy provided for double indemnity if the insured should die directly from bodily injury effected solely through external violent, and accidental means, with the proviso, however, that if such accidental death should result directly or indirectly from bodily or mental infirmity or disease double indemnity would not be payable. On Nov. 19, 1930, the insured in entering a building through a window, stepped on a table, which shot from under him, throwing him on his back on the cement floor. He had theretofore always been apparently well and vigorous. Immediately after the accident he appeared to be in pain and gave indications that his back was bothering him. Within a few days he became acutely ill and vomited, he lost his appetite and was not as active as formerly. On December 15 purple spots were seen on his legs and marks on his back. His hands and feet were swollen. He was taken to a hospital for observation where he grew steadily worse. He died Dec. 27, 1930 while undergoing an operation "to relieve an accumulation of gas." It was found that he had a chronic inflammation of the gallbladder, and gallstones, of apparently long standing. The insured died, according to the report of the case of "a degeneration of the liver, causing purpura which appears to be a breaking down of the blood vessels resulting in hemorrhages throughout the body."

Apparently, the insurer was willing to pay the face value of the policies but unwilling to pay double indemnity, to which the beneficiary was entitled only in event of death by accident. The beneficiary under the policy therefore brought suit. Three of the physicians who testified as experts for the plaintiff gave it as their opinion that the degeneration of the liver that caused the death of the insured was due solely to the accident and that the chronic condition of the gallbladder neither caused nor contributed to the death. On the other hand, two physicians who testified as experts for the insurer were of the opinion that the degeneration of the liver was caused by infection from the diseased gallbladder. All the medical witnesses however admitted that purpura might be caused either by trauma or by infection. The question of fact, then, was whether the degeneration of the liver in this case was (1) caused solely by the accident or (2) caused in whole or in part by the diseased gallbladder. This issue was clearly submitted to the jury which found in favor of the plaintiff in effect finding that the fatal degeneration of the liver was caused solely by the accident. Thereupon the insurer appealed to the United States circuit court of appeals eighth circuit.

The insurer contended that, even if the accident was the sole cause of the degeneration of the liver, still the insurer was not liable for double indemnity, the degeneration of the liver was itself "a disease" and therefore the insured died "directly or indirectly from bodily infirmity or disease." The language of the policy, however, said the circuit court of appeals, cannot be regarded as excluding from double indemnity coverage a death that results from a disease that is itself directly and solely caused by an accident. After having promised double indemnity for accidental death, it would take clear and precise language to limit the coverage of the policy to only such a death as is caused by an accident which produces no condition recognized as a disease.

The insurer further contended that the only inference that could be drawn from the evidence was that the condition of the gallbladder of the insured either caused or contributed to his death. The mere fact that the insured had a disease at the time of the accident, said the circuit court of appeals, does not prevent a recovery for accidental death if the disease had no causal relation to the death. Whether death was caused solely by the accident or wholly by the diseased gallbladder, or partly by the accident and partly by the diseased gallbladder, was clearly for the jury to determine and the jury's finding is conclusive. The trial court correctly charged the jury.

If Mr. Still [the insured] sustained an accident but at the time it occurred he was suffering from a pre-existing disease or bodily infirmity and if the accident would not have caused his death if he had not been affected with the pre-existing disease or infirmity, but he died because the accident aggravated the effects of the pre-existing disease or bodily infirmity or because the pre-existing disease aggravated the effects of the accident then the defendant would not be liable under the double indemnity provision of the policies because in such a case the death would be caused partly by disease and partly by accident. But even if the death was caused by a disease which disease was not the result of any other bodily infirmity or disease in existence at the time of the accident but which disease was itself caused by the external violent and accidental means which produced the bodily injury the defendant would be liable to pay the double indemnity because in such case the disease was the effect of the accident.

A judgment in favor of the plaintiff, the beneficiary under the policies contested, to recover double indemnity, was affirmed—*Mutual Life Ins Co of New York v Still*, 78 Fed (2d) 748.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Large Doses of Calcium in Metastatic Carcinoma in Bone.—Brunschwig cites two cases of metastatic carcinoma to bone from the breast (diagnosed roentgenologically) in which intensive calcium therapy was the apparent cause of a temporary sclerosis of the skeleton, with partial or almost complete filling in of many of the osteolytic lesions by bone. The severe pain accompanying these lesions was greatly relieved for long periods. No opiates or other analgesics were administered during the periods of symptomatic improvement. In one case there was a return to normal physical activity for one and one half years. No roentgen therapy was administered to these patients during or prior to the periods in which temporary sclerosis of the skeleton occurred. In five other patients exhibiting osteolytic metastases from carcinomas of the breast, intensive calcium therapy, while affording in three instances some degree of amelioration of pain, failed after three, four and six months respectively to produce roentgenologic evidence of changes in the normal or involved portions of the skeleton. The fact that only two of seven cases responded to calcium therapy by showing roentgenologic evidence of osteosclerosis in the lesions and uninvolved bones is unexplained. The various factors that affect calcium balance were not taken into consideration during the periods of observation. Perhaps adjustment of these factors preliminary to and concurrently with intensive calcium therapy would have altered the incidence of sclerosis of the skeleton. The diagnosis of metastatic carcinoma to bone in these cases is only roentgenologic but in the author's opinion no other condition under the circumstances could have caused the changes seen in the initial roentgenograms. No postmortem studies are available at this time.

Sternoclavicular Branchioma.—Fried presents two cases which showed a unilateral neuritis of the brachial plexus, a homolateral Horner's syndrome and an atrophic monoplegia of the corresponding arm. Roentgen examination of the affected side showed a dense shadow confined to the region of the first

three ribs. The entire clinical course of the malady was dominated not so much by the malignant disease as by the proximity of the tumor to the brachial plexus, on which it had encroached. Postmortem examination revealed a squamous epithelial cancer originating in the region of the left sternoclavicular articulation, ultimately invading the infraclavicular and supraclavicular fossae, the clavicle and the upper three ribs. The pleura, the lungs and other viscera were free from tumor. The probable origin of the tumors from epithelial rests of the lower cleft of the branchial apparatus is discussed, and in accordance with their origin they are designated as "sternoclavicular branchiomas." Early recognition of the tumors is emphasized.

Cytologic Study of Benign and Malignant Tissues.—Fidler reviews the grounds on which the cytologic in contradistinction to the histologic diagnosis of malignant conditions may be made and presents evidence obtained from a study of 150 benign malignant tissues. He used the technique of Dudgeon and Patrick, who stress the importance of preparing the film immediately after the tissue is removed from the body. This, in the author's experience, is not necessary. Equally satisfactory smears can be prepared from tissues kept in water or saline solution for four hours. The smear, however, should be made from a freshly cut surface. The cut surface of a benign tissue when scraped with a sharp knife usually yields few cells. Those that do come away are characteristically in sheets or clumps, thus making a very irregular smear both grossly and microscopically. The cells are usually no more than one layer in thickness and have a flagstone or pavement arrangement. The cytoplasm stains pink and has a regular outline. The size and shape of the cell and nucleus are very regular. The smallest nucleus is never less than half the size of the largest, and usually the variation in nuclear size does not exceed 3/4. The fibrin network and chromatin material are fine and delicate. The nucleolus may be single or multiple, but its total area is small in comparison to the nucleus. It is round or oval and regular in size and shape. A typical malignant tissue presents an entirely different picture. The cells have no regular arrangement, and the pavement structure is never seen. Normal cells are adherent one to another because of the presence of a cement substance between the individual units. The absence of this adhesive quality is a striking feature of malignant cells. The cells are irregular in size and shape, and frequently the cellular outline is broken. The cytoplasm tends to stain more darkly than in benign cells and may contain inclusions of leukocytes, red blood cells and other protein debris. In making a diagnosis, the examination of the nucleus and its constituents is probably of the greatest importance, for, while the cytoplasm may be broken or even so completely disrupted as to render the nucleus naked, the nuclear membrane affords sufficient protection so that the outline and contents are undamaged. The nucleus is characterized by coarseness of all its elements. There is no regularity in its situation in the cell, but it is usually eccentrically placed. It is larger than usual and varies greatly in size and shape. The nuclear chromatin stains more deeply and may be found in large granules. The presence of multinucleated giant cells is the rule rather than the exception. The nucleolus is very large, single or multiple, and frequently has an irregular outline. It stains a pale red or violet and is sometimes surrounded by a clear halo, which forms a striking contrast. The author concludes that the results of his work seem to corroborate the contention of MacCarty, Dudgeon and Heiberg that the malignant cell is a morphologic entity and can be recognized in suitable preparations.

Pertussis Immunization—Kendrick and Eldering made a progress report on a pertussis immunization study in Grand Rapids, Mich. The series to date includes 1,592 children—712 in the test group and 880 in the control group. In the whole series there have been sixty-seven cases of whooping cough, of which sixty-three occurred among the controls. The data presented suggest that an active immunity has followed the injection of *Bacillus pertussis* vaccine under the conditions described. However, before a proper evaluation can be made of the data or definite conclusions drawn it will be necessary to increase the number of subjects in the study and to await the accumulation of follow-up data over a longer period of time.

Pelvic Pain in Women—Kindel believes that the hypogastric plexus carries the important pathways of sensation from the internal genital organs to the medullary centers and that section of the superior hypogastric plexus is a safe, simple and

efficacious way of interrupting these pathways. He believes that resection of the superior hypogastric plexus has a definite place in gynecologic surgery but should be employed in carefully selected cases. It is not to be used as an immediate procedure in all cases of plexalgia, particularly in the true adolescent girls, whose first few periods may be irregular and painful. In many instances this pain disappears in a few years and especially after a pregnancy. He feels certain that failure to recognize this type of pelvic pain (plexalgia) accounts for some of the poor results in gynecologic surgery. This is evident in the fact that one fourth of his patients had been operated on previously.

Use of Nupercaine Ointment in the Eye—Minnich used the commercial nupercaine ointment, which contains 1 per cent of the anesthetic base in hydrous wool fat and petrolatum, for the relief of pain from trauma to the eye in 105 cases. The results from the outset were most gratifying. Within three to five minutes following application of the ointment to an injured eye, there was usually entire relief from pain, relief which persisted more or less completely for twenty-four hours in the majority of instances. When necessary the eye is cleansed with some mild antiseptic douche, any foreign body is removed and then a small amount of the ointment is applied to the injured eye. In no case is the patient supplied with the ointment for use at home, but he is instructed to report the following day. In a large proportion of the cases a single application of the ointment was required, in others, two or more were necessary. In one patient, seen some time after severe burns of the cornea with wet cement and at the time of first examination presenting, as the result of neglect, a well defined corneal ulceration, the ointment not only relieved the discomfort but its daily application for sixteen successive times was followed by progressive improvement in the ocular condition. In none of the 105 cases was there the least indication of an injurious effect from the ointment on the cornea, and all patients continued to work at their usual occupations.

Pulmonary Rest by Posture—In questioning patients with pulmonary tuberculosis, Pierson and Newell found that some had no preference as to position and that many preferred to lie on the side of their good lung. Animal and clinical investigation revealed that the mediastinum falls toward the down side according to its flexibility. The (essentially hydrostatic) pressure of the abdominal viscera pushes the diaphragm cephalad on the down side but exerts practically no pressure cephalad on the up side (average 15 cm water pressure greater on the down side than on the up side). The increased motion of the diaphragm on the down side is aided by the fact that a muscle

under tension reacts more actively, inspiration being a thrust against the pressure of the abdominal contents. Quiet expiration is a passive motion. On the up side it is done by the elastic recoil of the lung, which diminishes as the lung contracts. On the down side it is done mostly by the subdiaphragmatic pressure of the abdominal contents, a force which continues practically undiminished no matter how far cephalad the diaphragm moves. To say that if a patient lies on one or the other side he automatically rests or splints the down lung is not borne out by these observations, and the reverse seems to be the fact. If rest of a lung is desired it may be obtained by paralyzing the phrenic nerve and having the patient lie on that side. The authors state that if their experiments with dogs are sound it is evident that there is not only more motion in the down lung but also more tidal air moved by that side.

Coexisting Syphilis and Tuberculosis—Guild and Nelson collected data on 20,281 tuberculosis patients (17,348 white, 2,933 Negro) on whom routine blood tests were made. Of these, 41 per cent of the white and 21 per cent of the Negro patients gave a positive Wassermann and Kahn reaction. Institutions that make a blood test only because of some special indication or at the request of the patient miss three out of every four cases of syphilis (syphilitic infection). Since the incidence of syphilis in this group is not significantly higher than one would expect to find in similar racial and age groups in the general population, the evidence suggests that syphilis does not predispose to tuberculosis. One third of all tuberculosis patients who have syphilis receive no antisymphilitic treatment whatever. While in most sanatoriums both the arsenicals and the heavy metals are used in the treatment of syphilis, a few use nothing but the arsenicals and others nothing but the heavy metals. Only in the use of neoarsphenamine was it possible to indicate the divergence of opinion as to the proper dosage. Here the authors found ten institutions using a fractional dose, sixteen a dose of average size, and one an amount considered high for routine administration even in a nontuberculous patient. It seems reasonable to expect that a study of a large number of case records will confirm or disprove Chadwick's opinion that syphilis lowers a patient's resistance to tuberculosis or that careful observation of a large series of cases would finally answer the question as to whether or not the coexisting syphilis should be treated. If so, the next step would be to determine the drug or drugs of choice under different circumstances and their optimal dosages.

Tannin Treatment in Tuberculosis—Loumos and Rosenblum used sodium tannate hypodermically in a solution of 0.5 per cent on alternate days in the intrascapular region in twenty unselected cases of tuberculosis, nineteen pulmonary and one lymphatic. The patients have taken tannin for from two and a half to five months so far. The treatment failed to show any benefit in six cases. These cases were progressive and probably in some of them the medication activated the process. In these cases the treatment was discontinued in the fourth or sixth week. In the other thirteen cases, six presented cavities and seven showed infiltration. Nine showed definite improvement clinically, progressive increase of weight, less expectoration, increase of appetite and strength and less pronounced rales. In the other four, while there was no increase in weight, the general condition improved as well as the appetite and strength, and the pulmonary signs became less pronounced. Roentgenologically seven improved definitely. Of these thirteen cases, three were slow, progressive, febrile cases, the fever in one disappeared after four months of treatment and in the other two became lowered. Four patients were improving slowly before the treatment but after that they improved rapidly. Six cases were stationary for several months and started to improve after the treatment. A 1 per cent solution was tried in the cases that failed to improve but without result. The medication was entirely harmless, as there were no reactions. In the case of bilateral cervical lymphadenitis an increase of the discharge was observed in the beginning of treatment followed by a lessening and finally disappearance after twenty injections. 1 cc. of the solution had been given on alternate days. At the same time in the enlarged lymph nodes without suppuration rapid swelling and suppuration were observed. Because of this reaction the injections were discontinued and

the sodium tannate was given by mouth with iodine. The amount given was 0.15 Gm of sodium tannate and 0.1 Gm of iodine daily, made in the form of a syrup. In this way reactions were avoided.

*Spina Bifida Treatment and Analysis of Eighty Four Cases I E Siris Brooklyn —p 97

Carbon Dioxide Absorption Technique in Anesthesia—Waters has observed more than 15,000 administrations with the completely closed or carbon dioxide absorption technique. It has been found pleasant and convenient from the standpoint of the anesthetist, the patient and the surgeon. The hospital management has found it economical. In 73.8 per cent of these cases the various agents were administered by the carbon dioxide absorption technique. The total mortality was 3.7 per cent due to respiratory (0.6), circulatory (0.9), anesthetic (0.05) and other (2.1) causes. The acquisition of a mastery of anesthesia in art and in practice, with a thorough appreciation of the underlying physiology and pharmacology, involves for the average medical graduate an intensive training of not less than three years. The knowledge and skill of the individual who administers an anesthetic drug is far more important than is the agent which he administers or the technique by which he administers it. A patient suffering from an injury to the brain enters the average hospital once in twenty days, whereas twenty patients in the average hospital have the brain and many other organs injured every day with anesthesia. The author does not mean to give the impression that the chemical absorption of carbon dioxide from anesthetic mixtures will revolutionize anesthesia but that only "the quality of the physician's care and skill" will do that.

Spina Bifida—Siris gives an analysis of eighty-four cases of spina bifida, forty-seven patients were not operated on. Of those not operated on, all but one had died within twenty-four hours to one year after admission to the hospital. Of the thirty-seven patients operated on there was a hospital mortality of 32.3 per cent and those who survived the operation have been followed for periods of from two months to ten years. Successful surgical intervention is dependent on the condition of the coverings of the protrusion, the contents of the dura and the extent of involvement of the nerve cord and brain tissue if present, the extent of the defect in the bony structure, and the degree of hydrocephalus and other congenital deformities and anomalies. The prognosis in infants who are suitable for operation is best when the operation is performed as soon after birth as the general condition permits, before unavoidable pressure produces ulceration and impending rupture with leakage of cerebrospinal fluid and ascending meningitis, marasmus or some intercurrent disease to which they are susceptible. The possibility that hydrocephalus may follow operative correction of a spina bifida should not cause one to defer intervention in a suitable case. Of the thirty-two children whose sacs were amputated hydrocephalus increased in seven of the eight children in whom it was previously present and it was precipitated in but four of the children in whom there was no previous evidence of hydrocephalus. Hydrocephalus was not increased in a child in whom the sac was preserved and it was not precipitated in four other children in whom the dura and arachnoid were retained. The preservation of the dural sac as advocated by Penfield and Cone

is recommended as the operative procedure of choice. The presence of a spinal or occipital herniation which is thin, tense and then ruptures and alternately closes and ulcerates with a discharge of cerebrospinal fluid, complicated by a slowly progressive hydrocephalus, does not in all cases contraindicate surgical intervention, as the results of some of the operations are gratifying.

Leprosy Associated with Diffuse and Progressive Atrophic Dermatitis—Pardo-Castello reports a case of diffuse and progressive cutaneous atrophy apparently due to leprosy. The unusual features were the universality of the atrophy, which affected practically the whole cutaneous surface except the palms and soles, the absence of other manifestations of leprosy and, finally, the awakening of the infection and the development of an acute attack of the disease following intramuscular injections of chaulmoogra oil. The clinical aspect as well as many features of the histologic picture were similar to, if not identical with those in the cases of chronic atrophic dermatitis reported in the literature. The only definite characteristics in the present case were the great number of vacuolated or foamy histiocytes in the cellular infiltrate and the appearance of lepra cells of Virchow and the presence of Hansen's bacilli in the lymph during the terminal acute outbreak.

Maggot Therapy in Dermatologic Practice—Ayres and his associates discuss the case of a chronic ulcerating granuloma of 7 years duration, in which the introduction of maggot therapy for eight weeks was followed by complete healing in another eight weeks. The result suggests the applicability of maggot therapy to other types of dermatologic conditions involving chronic ulcerative or granulomatous processes such as amebic ulceration of the skin, coccidioidal granuloma and spreading ulcerative and gangrenous infections of the abdominal wall, which occasionally follow appendectomy. There is psychic resistance to be overcome in instituting this type of therapy.

Coccidioidal Granuloma—Jordan and Weidman are of the opinion that *Coccidioides immitis* is firmly established as the cause of most if not all, cases of North American coccidioidal granuloma as at present recorded. It also caused two cases in Argentina. A radically different fungus *Paracoccidioides brasiliensis* is the cause of numerous cases in Brazil of a disease which heretofore also has been regarded as coccidioidal granuloma. The authors secured two strains of the latter fungus and compared them with two North American strains of *Coccidioides immitis*. They proved to be radically different in culture tubes and under the microscope and as to pathogenicity for laboratory animals. Only in tissue was there any resemblance between the two parasites, yet even there certain differences could be established. They believe that *Paracoccidioides brasiliensis* constitutes a new species. In view of the widely differing character of the diseases produced by the two species, it is doubtful whether the disease produced by *Paracoccidioides brasiliensis* should be included in the category of

coccidioidal granuloma. It is recommended that the name "Almeida's disease" be applied to the maladies caused by *Paracoccidioides brasiliensis*. Previously reported knowledge of North American cases of coccidioidal granuloma should be reexamined in the full light of Almeida's disease. *Paracoccidioidal granuloma* is a third fungous disease that must be added to blastomycosis and coccidioidal granuloma when the problem arises of differentially diagnosing blastomycosis from coccidioidal granuloma either clinically or histologically.

Local Quinine Therapy for Some Eye Diseases—According to Selinger, quinine locally is a bactericide and astringent and is slightly anesthetic to mucous membranes. It possesses the property of penetrating through mucous membranes when applied locally, and by its action as a protoplasmic poison it causes the destruction of leukocytes, lymphocytes and other cellular elements. It also inhibits the invasion of the tissues by these cells. These well known pharmacologic properties explain the favorable therapeutic action of quinine bisulfate in cases of trachoma, interstitial keratitis, old corneal opacities and a few other diseases of the conjunctiva and cornea.

- *Role of Allergy in Arthritis W. T. Wootton Hot Springs National Park—p. 119
- Malaria in Arkansas W. B. Grayson G. Hastings H. V. Stewart and Mildred M. Moss Little Rock—p. 123

Role of Allergy in Arthritis—Wootton gives allergy the stellar role in the initial manifestation of arthritis. Practically all nonseptic disturbances of the joint begin as an allergic reaction, comparatively few as a trauma. The simple allergic joint, that is the acute gonorrheal, acute rheumatic fever, gouty and traumatized joints all show the same lack of pathologic and roentgenologic observations, only an edematous swelling is apparent. Chronic arthritis is the result of a dual process. Hyperparathyroidism is necessarily concomitant with the allergic or edematous process before any change may take place in the bone. The hormone from the parathyroids is the only known endocrine agent that may cause a hypercalcemia. In the event of a hypercalcemia occurring at a period when there is no synovial disturbance the calcium is taken up from the trabeculae, causing osteitis fibrosa cystica, Paget's disease and similar conditions. On the contrary, an atrophic arthritis results. Bacterial allergens from foci of infection predominate in the early life of the arthritic patient, and food proteins later. The two may be active at the same time. In the latter years kidney permeability to the excess of calcium, phosphorus and magnesium may bear a definite relation to a redeposit constituting the hypertrophic type of arthritis. The parathyroids are inaccessible and too little understood to bear tampering with by the inexperienced. A vast amount of research work remains to be done before this theory can be proved or disproved or

add greatly to the protective measures needed. As a basis for the study of arthritis, this theorem offers a plausible outline for a regimen that should both prevent and alleviate arthritis.

*Treatment of Asthma with Ethylhydrocupreine W C Service, Colorado Springs—p 24

Treatment of Asthma with Ethylhydrocupreine—Service gave ethylhydrocupreine to sixteen patients, eleven of whom showed favorable results, while five were not benefited. Ethylhydrocupreine was used in doses of 4 grams (0.25 Gm). The patient is instructed to eat no breakfast and to take no medication by mouth during the morning. One capsule is taken at 8 a m and one at 10 a m. With each capsule, 8 ounces (240 cc) of milk is taken and as much more allowed as is desired. The noon and evening meals are taken as usual and any oral medication during the afternoon and evening. The next two mornings the same schedule is repeated. Then a rest of two days is given and the program is repeated. Following a second course, the treatment should be individualized. Some may be free from asthma and remain free. Others may remain free by taking one capsule each day for two or three days, and then following it with a period of rest. The object is to get the patient on as small a dosage as will keep him free. Most patients will remain free after two months of treatment, and then an occasional dose should be given if early signs of asthma appear. Patients who obtain relief with ethylhydrocupreine will notice first that the attacks do not occur in acute spasms, but that a gradual tightness of the chest develops. Expectoration is increased slightly and, instead of being difficult to raise, it is brought up easily and this usually serves to relieve a spasm of the chest. The relief from the terror of fighting for breath is marked in those patients who have spasmodic coughing attacks, because the mucus is raised without effort. The drug may be productive of toxic symptoms and should be discontinued in cases in which the patient complains of tinnitus, gastrointestinal distress or visual disturbances. Patch tests may give valuable information as to drug idiosyncrasy. The drug is not without danger, therefore each patient should be put on a minimal dosage.

Effect of Lumbar Sympathectomy on Growth of Paralyzed Legs—Harris and McDonald believe that prolonged increase in the blood supply to the lower extremity of a growing child can result in acceleration of the growth of the involved extremity. The increase in blood supply that follows lumbar sympathectomy is capable of inducing acceleration of the rate of growth. The shortness that follows paralysis of the lower extremity from poliomyelitis is due to the loss of accessory factors that normally enhance the basic growth rate of the epiphyseal line. The known factors are the contractions of normal muscles and the maintenance of a normal blood supply. Under appropriate circumstances, lumbar sympathectomy will diminish the shortness due to poliomyelitis. The factors favorable to a good result are paralysis limited to one lower extremity, paralysis moderate in degree, early operation (at the age of 6 years, if possible), use of ganglionectomy rather than ramsection, and maintenance of the increased vascularity that follows the operation.

Sacrarthrogenetic Telalgia—Pitkin and Pheasant base their study on an analysis of 506 examinations for low-back disability, chosen from a series of nearly 1,000 because of their completeness. Its scope is limited to a study of the pain caused by lesions of the sacro-iliac and sacrolumbar joints, and its purpose is to advance the following definition in the interest of more accurate anatomic nomenclature. "Sacrarthrogenetic telalgia" is in no sense a diagnosis but is a descriptive term that should be applied to the typical syndrome of pain originating in the sacro-iliac and sacrolumbar articulations and their accessory ligaments. The referred pain (telalgia) affects the gluteal or the sacral region, or both regions, and may affect any part or all parts of the lower extremities and genito-inguinal regions except the internal erural and plantar regions. The lesions that produce this type of pain are associated with lateral spinal scoliosis. They do not cause objective neuro-pathologic manifestations other than reflex physiopathic disorders and the atrophy of disuse. Sacrarthrogenetic telalgia is

not the result of irritation or compression of the trunks of peripheral nerves and must not be confused with radiculitis, neuritis or neuralgia. When caused by intra-articular ligaments, telalgia appears only in the intergluteal triangle. Pathologic changes in the tension of, or irritative stimuli applied to, the extra-articular ligaments of the upper sacral joints cause telalgia in the lower extremities. Telalgia that affects the lateral crural region originates in the posterior sacro-iliac and sacro-ischial ligaments. In presenting the results of their clinical and anatomic research, the authors have included only those observations which are related to the following sources of confusion in sciatica and low-back pain: (1) the inaccuracy of the nomenclature of referred pain, (2) the influence of inaccurate nomenclature on pathologic concepts, (3) the difference of opinion with regard to the localization of dermatomic areas, (4) the lack of specific descriptions of the innervation of the upper sacral joints and their ligaments, and (5) the vague descriptions of tenderness of various anatomic structures.

Treatment of Clubfoot—Brown has found that marked overcorrection of all the deformities of clubfoot can be obtained by the use of continuous slight traction by means of elastic bands. Since this method has been followed, it has not been necessary, in children up to the age of 5 years, to use forcible manipulations, ether, tenotomies, or stretching by frequently changed plaster casts or adhesive plaster.

Peripheral Resistance in Arterial Hypertension—Prinzmetal and Wilson attempt to show whether the increased peripheral resistance is generalized throughout the systemic circulation or is confined to the splanchnic area to what extent the vessels are responsible for the increased peripheral resistance capable of dilatation, and what part is played by the vasomotor nerves in the maintenance of the increased peripheral resistance. *i. e.*, if arterial hypertonus is present, whether it can be attributed to an increase in sympathetic vasoconstrictor impulses. Determinations of resting blood flow in the arm in various types of hypertension (benign, malignant and secondary) give an average value no greater than that obtained from subjects with normal blood pressure. This indicates that increased vascular resistance in the different types of hypertension is not confined to the splanchnic area but is generalized throughout

the systemic circulation. Patients with hypertension show increase in blood flow in response to heat and reactive hyperemia equal in degree to that produced in normal individuals, showing that the blood vessels in hypertension are capable of considerable dilatation and indicating that the increased peripheral resistance is due to hypertonus and not to organic changes in the vessel walls. Sympathetic vasodilatation produced by the "heat test" produces no greater increase in blood flow in subjects with high blood pressure than in normal individuals, suggesting that the vascular hypertonus is not vasomotor in origin. Patients with coarctation of the aorta, on the other hand, show a greater increase in blood flow in the arm in response to the heat test than controls or patients with generalized hypertension. This demonstrates that vasoconstriction of sympathetic origin is present in the upper extremities in coarctation of the aorta and affords confirmatory indirect evidence that the hypertonus in generalized hypertension is not of vasomotor origin. Anesthetization with procaine hydrochloride of the vasomotor nerves to the arm produces the same increase in flow in normal subjects and patients with hypertension, proving that the vascular hypertonus is independent of the vasomotor nerves and that this hypertonus must therefore be regarded as intrinsic spasm of the blood vessels themselves. Acute exacerbation of hypertension with change from the benign to the malignant type has been observed in one case. Such exacerbation is apparently not due to increased vasomotor activity but must be attributed to an increase in the intrinsic vascular hypertonus. These conclusions apply to all types of hypertension and, hence there is no physiologic evidence for the separation into "organic" and "functional" types or for the assumption that renal hypertension is due to vasomotor hypertonus. In blood vessels of the arm greater variations in blood flow are produced by vasodilator than by vasoconstrictor impulses. It appears that normal vasomotor activity is superimposed on the intrinsic vascular hypertonus. Surgical procedures aiming at the relief of high blood pressure by sympathectomy do not abolish the vascular hypertonus that is fundamentally responsible for the hypertension.

Macrophage System of Lungs in Pneumonia—Robertson and Uhley made a histologic study of postmortem tissues obtained from forty cases of lobar pneumonia representing more than ninety separate lesions of the lobe of approximately known age, with the purpose of ascertaining whether or not the macrophages play as conspicuous a part in the later stages of the human pathologic process as was observed in the lesion of experimental lobar pneumonia in the dog. It was found that resolution of the consolidated lung was regularly accompanied by characteristic changes in the lung parenchyma and cellular exudate analogous to those occurring in the dog's lung at the time of recovery. The evolution of the whole process could be followed often in a single case when lesions of different ages were present. The first evidence of the reaction consists of an increase in the number of large mononuclear cells in the alveolar walls, many of which protrude into the air spaces. This results in a thickening of the septums. As the process develops, the large mononuclear cells become detached from the alveolar wall and enter the exudate where they exhibit the form and phagocytic functions of the macrophages. These cells gradually replace the polymorphonuclears, the fibrin disappears progressively, and the lesion assumes the characteristic appearance of resolution. The same type of tissue cell reaction was observed in the lymph nodes at the hilus of the lung. Sections obtained from six patients dying at intervals of from six days to two months following recovery from lobar pneumonia showed a pronounced macrophage reaction in every instance. Whenever a well developed macrophage reaction occurred, pneumococci were observed to be few in number or absent while micro-organisms were abundant in the majority of lesions of all ages in which the exudate was composed predominantly of polymorphonuclear leukocytes. Such marked differences in numbers of pneumococci were observed not only between lobar lesions but also at times in different parts of the same lesion in which areas of focal macrophage reaction were occurring. The macrophages were seen to be actively phagocytic and gave evidence of effective digestion of engulfed pneumococci. These data suggest that mobilization of the macrophages represents an immune response of the pulmonary tissue cells.

Method of Closing Suprapubic Bladder Incisions—To shorten the period of disability and assure better healing Day diverted the urinary drainage entirely away from the operative incision in the abdominal wall and allowed the incision to heal by primary intention. The technic involved was a modification of the Pfannenstiel incision as adapted to bladder operations by MacGowan, Legueu and Kelly. The incision is made in the usual way except that it lies 4 or 4.5 cm above the upper border of the symphysis. A mushroom drain is sutured into the bladder. The bladder is then protected by a finger in the prevesical space, and a stab wound is made from the outside through the middle of each rectus muscle and half way between the incision and the symphysis. A large curved clamp is passed through this stab wound. With it the drainage tube, a Dakin tube and a cigaret drain are drawn out together through the stab. The cigaret drain and the Dakin tube are then arranged so that they lie properly in the prevesical space, and the Dakin tube is tied to the drainage tube on a level with the skin. The incision is closed tightly in layers. The suturing of the recti closes the incision off completely from the prevesical space. The cigaret drain should not be constricted. It is withdrawn as usual on the second or third day while the Dakin tube remains in place from five to seven days, so that if any signs of infection in the prevesical space appear treatment with dilute solution of sodium hypochlorite can be begun at once. If this is necessary, it must be vigorous. Injections should be made every one or two hours day and night. If there is any evidence of alkaline infection dilute acetic acid of a strength sufficient to neutralize the wound should be used until the ammoniacal odor disappears and then hypochlorite solution substituted. The sinuses produced tend to contract rapidly probably because they are closely surrounded by the muscle tissue of the rectus. Leakage of urine around the tube is rare and the fistula tends to close quickly after the tube is removed. The author performed the operation in one case of impermeable stricture two

cases of prostatic hypertrophy with difficult catheterization and massive hemorrhage, and two cases of prostatic hypertrophy with severe infection and acute epididymitis. Drainage was maintained from five to 117 days. Four of the cases healed by primary intention, and the fifth, while infected, was healed at the end of seven days.

Toxic Hyperplasia of Prostate Gland—Barnes carried out animal experiments in order to determine whether sterile prostatic secretion is toxic and, if so, its effect on animals in comparison with other substances of known toxicity. The work shows that prostatic secretion which contains no pus is quite toxic when injected into mice, rats and other animals, the toxicity of 1 cc being comparable to that of one-fourth grain (0.016 Gm) of morphine. The author believes that an excessive amount of prostatic secretion retained in the prostate results in absorption of this toxic substance, with resulting general and local toxic symptoms. He applies the term toxic hyperplasia of the prostate to this condition.

Skin Test for Diagnosis of Gonococcic Infections—Corbus states that the standard bouillon filtrate (Corbus-Ferry) contains two specific substances. The one, when injected intradermally is probably taken up by the histiocytes in the skin and produces a gonococcus antitoxin. The other presumably combines with the sensitizing antibodies and produces a typical allergic response in individuals infected with the gonococcus. These two reactions are easily demonstrated after twenty-four hours following a therapeutic dose of the bouillon filtrate. There is a large inflammatory zone, usually about 2 inches in diameter (antitoxin forming area), in the center of which is a smaller elevated and darker red zone (sensitizing response). However, when the bouillon filtrate is heated in an autoclave at 15 pounds pressure for fifteen minutes for two periods with average temperature of from 115 to 120 C, the antitoxin forming substance is destroyed and there remains a substance capable of eliciting a cutaneous response in individuals infected with the gonococcus. Having observed in a woman infected with the gonococcus what appeared to be a cutaneous wheal in the center of the inflammatory area produced by a therapeutic dose of bouillon filtrate, it appeared to the author that a similar reaction for diagnostic purposes might be obtained by using the filtrate. In order to prove definitely that the body is sensitized during gonococcic infections and that it is capable of giving an allergic response to the gonococcus protein contained in the gonococcus bouillon filtrate when injected intradermally, experiments were carried out which showed that the cutaneous test is founded on an allergic basis. The fact that this allergic state ceases with the disappearance of the gonococci may help to clarify many previously mistaken diagnoses and, in addition, furnish a specific test for a clinical cure.

Placental Extract in Control of German Measles—An opportunity to study the use of placental extract in the control of German measles came to Gottlieb during an epidemic in the Central Maine General Hospital and vicinity during April and

May 1935 The dosage administered by the various workers has been chosen arbitrarily from 5 to 2 cc intramuscularly May 16 the author gave sixteen nurses 4 cc of placental extract intramuscularly, and from that date to May 29 forty-six of the hospital personnel received 0.2 cc of the extract intradermally None of this group had given a history of having had German measles previously None of those receiving the large intramuscular dose (4 cc) or the small dose (0.2 cc) intradermally contracted the disease Nine cases of German measles were contracted during that period by a group similarly exposed, but who had not received the extract by either route Those who received 4 cc of the extract intramuscularly complained of soreness at the site of inoculation for a period varying from one to three days Those receiving 0.2 cc intradermally developed areas of erythema and tenderness measuring from 2 to 10 cm in diameter, which disappeared in from three to five days No systemic reactions were noted in either series

Syphilis and Cardiovascular Disease—Weber bases his discussion on a review of syphilitic cardiovascular cases from the Nashville office and a review of the current literature He finds that 1 Next to the rheumatic and hypertensive arteriosclerotic groups of heart disease, syphilis is the most important etiologic factor in the production of cardiovascular disease Men are affected more often Negroes suffer more often from cardiovascular syphilis than white people, the ratio being about 3 to 1 2 Aortitis is by far the most frequent manifestation of cardiac syphilis, aortic insufficiency and aneurysm closely following in frequency Pure aortic insufficiency, aortitis and aneurysms, especially in persons in the fourth and fifth decades, are at least 90 per cent syphilitic Direct syphilitic infection of the mitral and the tricuspid valve is so rare that some authors question its existence 3 The condition underlying a syphilitic aortitis is an obliterative endarteritis of the vasa vasorum of the adventitia of the aorta, causing the intima to wrinkle and to lose its elasticity The aortic wall weakens and stretches The cusps of the aortic valve have a tendency to separate bringing on a regurgitation, in contrast to the rheumatic infection of the aortic valve, which has a tendency to unite the cusps causing stenosis The heart is enlarged in most cases of aortic insufficiency 4 Many years elapse between the onset of the infection and the appearance of cardiovascular symptoms, the average being from fifteen to twenty years 5 The most frequent and early symptom is dyspnea, either on exertion or of the paroxysmal type Precordial or substernal pain comes next in frequency Giddiness palpitation, nervousness and swelling of the ankles are commonly complained of Signs found on physical examination in aortic insufficiency differ from those in aortitis 6 A positive Wassermann reaction is found in the great majority of syphilitic heart cases in from 80 to 90 per cent X-rays, electrocardiographic tracings and oscillometry are other auxiliary methods helpful in arriving at a correct diagnosis 7 In the seventy cases reviewed the most prominent symptoms referable to the heart were shortness of breath in 85.7 per cent pain over the chest in 60 per cent, dizziness in 20 per cent nervousness in 14.3 per cent and hoarseness, edema, cough and loss of sleep in 28.6 per cent A diastolic murmur

over the base was found in every case of aortic insufficiency A harsh systolic murmur was elicited in cases of aortitis without aortic insufficiency, the second aortic sound having a ringing quality The average pulse pressure in the aortic insufficiency cases was 102 Enlargement of the heart or/and the aorta by percussion and roentgen examination was discovered in 71 per cent A positive Wassermann reaction was shown in 72.8 per cent

Trichiniasis in Louisiana—Hinman made a routine study of 200 consecutive necropsies from the State Charity Hospital of Louisiana infants were omitted Small pieces of diaphragm muscle measuring about 2 inches square were obtained, finely ground up and placed in a 1 per cent solution of pepsin with 0.5 per cent hydrochloric acid About 200 cc of the solution was used for each 10 Gm of muscle, following the technic of McCoy (1931) This mixture was placed in an Erlenmeyer flask in an incubator at 37 C for from five to six hours, during which time it was stirred continuously By this method most of the muscle was digested, liberating the capsules if present The material was strained through wire gauze into a funnel, which was closed by a rubber tube and pinchcock Sedimentation was allowed to go on for one hour after which a few cubic centimeters was drawn off from the bottom of the funnel and examined microscopically for the encysted capsules or larvae Of the 200 human diaphragms examined seven (3.5 per cent) were found to contain encysted larvae of *Trichinella spiralis* From the numbers of larvae found in the diaphragms

these cases must have been rather light infestations and probably produced few if any clinical manifestations. Serial sections failed to reveal any embryos in those instances in which the method was used. In two of the seven cases larvae were found active within the capsules, indicating that the infection had not been present long. The existence of a 35 per cent infestation with *Trichinella* points to the fact that trichiniasis cannot be regarded as a public health problem of no significance in Louisiana. Careful differential diagnosis should reveal the presence of clinical cases in this state. The digestion technique could be utilized in the examination of biopsy material from suspected cases and may demonstrate larvae that are too few to be found by serial section.

Duodenal Carcinoma—Startz reports a rare case of duodenal ulcer of the supra-ampullary portion of the duodenum combined with an independent primary carcinoma of the ampullary portion of the duodenum both of these lesions were visualized clearly in roentgenograms. The patient died from internal hemorrhage—an erosion of a blood vessel within the duodenal ulcer. There were no signs present of intestinal obstruction. The patient was 34 years old. Metastasis was present to adjacent lymph nodes and the liver. Brill states that metastasis even to the contiguous lymph nodes is not common. The patient was not jaundiced. Eger states that in cases of carcinoma of the ampullary portion of the duodenum jaundice generally appears early. The roentgenologic study is properly performed is the strongest link in the chain of diagnostic

methods. The well trained roentgenologist should be capable of detecting an 'organic' lesion in the small intestine. However, an attempt to specify the exact nature and site of the lesion is often a shrewd guess and may result in a fantastic roentgen diagnosis out of gear with that of the necropsy report. The presence of symptoms and physical observations suggesting a gastro-intestinal malignant condition (including absence of free hydrochloric acid in gastric contents and presence of occult blood in stools), together with the recognition of a small intestinal organic lesion roentgenologically, should spell a preoperative diagnosis of carcinoma of the small intestine.

Hypercalcemia and Hypophosphatemia Simulating Hyperparathyroidism—Birk and Huber cite three cases from the study of which it is apparent that signs of decalcification in roentgenograms were lacking as well as other symptoms of hyperparathyroidism. But one constant feature in each case was hypercalcemia and hypophosphatemia and this would strongly suggest hyperparathyroidism were it not for the fact that other definite signs were discovered. It is possible that in cases 1 and 3 there was a metastasis to the parathyroid with the consequent features simulating hyperparathyroidism and that in case 2 there was syphilis of the parathyroid causing secondary hyperparathyroidism. No postmortem studies were obtained in patients 1 and 3 and patient 2 is still alive. The authors wonder whether hypercalcemia and hypophosphatemia should be emphasized as pathognomonic of hyperparathyroidism at all or should rather be considered a secondary phenomenon caused by the excessive bone destruction in certain diseases which may involve the skeletal system. This view is opposed by Cantarow and Hare. It appears to the authors that a further study of blood calcium and phosphorus in malignant diseases and syphilis should be made. They believe that, when similar changes are observed no matter how small the percentage may be a parathyroidectomy would hardly be in order in every case of hypercalcemia and hypophosphatemia.

Sedimentation Rate in Juvenile Rheumatism—Payne and Schlesinger confirm the close relationship between rheumatic activity and the sedimentation rate. Acute tonsillitis and influenza may both cause more than a temporary rise in the sedimentation rate. This must be remembered when the test is used as possible evidence of active rheumatism. Chronic tonsillar infection on the other hand does not as a rule have any appreciable effect on the sedimentation rate. In acute chorea there is only a small, transient rise of the sedimentation rate. This may even be absent. No indication is given by the sedimentation rate of the possibility of subsequent cardiac involvement. In congestive cardiac failure the sedimentation rate frequently falls to normal even in the presence of active disease. This is a bad prognostic sign. The test is of value in detecting subacute rheumatism and miniature rheumatic fever following tonsillitis. When nodules are present the test has a prognostic significance. Fall of the sedimentation rate heralds their disappearance. In nonactive cases there were 140 children with no evidence of active rheumatism during the period of observation. Seventy-four of these had no signs of cardiac involvement and, with three exceptions, showed no rise in the sedimentation rate apart from intercurrent infections. There was no apparent reason for the raised values (17, 21 and 29 mm maximum) in three cases, except for tonsillar sepsis in one instance. Sixty-six children had had heart disease at some time or other. The sedimentation rate was normal in fifty-six and raised in ten. This rise was transitory in five. Active rheumatism was present in eighty-nine cases. Sixty-six showed rapid improvement and were finally considered no longer active from the clinical standpoint. The sedimentation rate showed a corresponding fall to normal in fifty-eight. In seven the sedimentation rate was higher or lower than was to be expected, and in one apparently quiescent case a fresh rise in the sedimentation rate appeared to herald a reawakened activity with chorea sometime after the patient returned home. The activity was marked and prolonged in sixteen cases. Here without exception the sedimentation rate was raised in close agreement with the clinical condition. Seven fatal cases occurred. All but one showed a raised sedimentation rate, but not so high as in many of the acute cases in which recovery occurred. Cardiac failure was prominent in the one case with normal values. Hence with every type of rheumatism there is close agreement between the sedimentation rate and the clinical picture, and this has been confirmed in many cases in this series by the subsequent history. In only twenty out of the 229 cases was there any discrepancy.

Skin Reactions to Products of Hemolytic Streptococcus—In an investigation of the relation of the hemolytic streptococcus to acute rheumatism, Gibson and Thomson performed intradermal reactions to an extract of a strain of that organism on 586 subjects, comprising rheumatic and control groups. The results suggest that great caution is necessary in interpreting any intradermal reaction. The possibility of altering the reactivity of the patient by a test inoculation is suggested. The results recorded with horse serum seem to be applicable to the various diagnostic skin reactions. For example the repetition of the double intradermal tuberculin test in cattle at short intervals might act as a sensitizing stimulus. The present study suggests that repeated intradermal tests not only sensitize but on a continuation of the series appear to

produce desensitization. Thus an irregular wavelike succession of sensitive periods is produced. Only 13.6 per cent of the Dick tests gave positive readings and, in the light of subsequent work, it appeared likely that these were not all true toxin reactions. From subsequent studies of fluctuations in the reaction to both the test and control reagents, besides the failure to neutralize certain of these reactions by antitoxin it would appear that some at least were simply the chance association of simultaneous reactivity to some constituent of the "toxin" fluid with temporary absence of reactivity to a constituent of the "control" fluid to which the individual might be at other times allergic. These observations suggest an explanation of pseudoreactions in which the control test is of greater size than the toxin reaction or even, as in some cases, when the control solution alone gives a reaction. The curves suggest that in the hypersensitive individual the principle responsible for pseudoreactions to toxin and control fluids may be regarded as different reagents, more or less distinct from one another so far as skin reactivity is concerned. The neutralization of reactions by homologous antiserum seemed to be related to some extent to the serologic type of the organism. The skin reaction characteristic of the allergy of infection is not neutralizable and there is no reason to think that any true antigenic toxin was responsible for the lesions produced. The results throw doubt on the conception of the skin reaction to extracts of hemolytic streptococcus as a true example of the allergy of infection, at least in adults.

Operation for Cleft Palate—Browne adopted a procedure which combined many borrowed points and a few original ones into an operation for cleft palate that was more satisfactory than any he had tried before. It depends mainly on the deliberate freeing of the two separated ends of the sphincter, complete with nerve and blood supply, and their suturing in a plane closer than normal to the posterior wall. There is first the preliminary operation of removing the tonsils and cutting the posterior palatine arteries. Three months later the final stage is performed. The freeing incision runs from the canine tooth in front backward just inside the teeth, then along the line of the pterygomandibular raphe, cuts the anterior pillar of the fauces off the tongue, and ends in the middle of the empty tonsillar fossa. Through this, by forcible blunt dissection, the mucoperiosteum of the hard palate the mucosa of the floor of the nose and the whole side of the nasopharynx are freed so that they fall inward and backward toward the posterior wall. Then from the bottom of the incision that frees the soft palate a double suture of forty day number 1 chromic catgut is passed right round the back of the throat. It enters the tissues opposite the tip of the uvula, emerges in the middle of the posterior wall of the pharynx, is reinserted through the same puncture, and emerges again through the corresponding point to its insertion on the opposite side. The stitch should run behind the superior constrictor exactly in the line of Passavant's ridge. The action of this posterior part of the sphincter should be imitated exactly by pulling on the catgut and rucking up the back of the throat. The ends of this suture are left hanging out of the mouth and the edges of the soft palate are deeply split. This split continues backward the gap between the mucoperiosteum of the hard palate and the nasal mucosa and runs gradually diminishing in depth to the tip of the uvula. The continuous nasal surface of soft and hard palate is then joined by interrupted sutures, plain ones for the nasal mucosa and vertical mattress ones for the soft palate. A ring suture is passed through the substance of the soft palate, just in front of the insertion of the tendon of the tensor palati crossing the half-sutured gap in the middle and returning to its original insertion in a complete circle.

round the line of the sphincter. It is left untied. The oral surface of the soft palate and the mucoperiosteum of the hard palate are joined by vertical mattress sutures, and any tiny gaps in the epithelial junction are closed. The soft palate thus constructed should lie much closer to the posterior wall of the pharynx than normal. The test of its proper construction is to make the patient gag, when the new mechanism should be seen to work properly at the first time, shutting the throat completely. The intratracheal catheter is withdrawn and the ring suture is tied. Its two loops are tied separately with several knots, tight enough to close the passage completely. The whole area is cleaned and swabbed with 1,000 acriflavine hydrochloride in petrolatum. Nonabsorbable sutures can be removed a fortnight after operation. The palates usually stiffen considerably from inflammatory infiltration during the first month and then slowly become more mobile again, in six months they are thin and thoroughly supple. The author used this method in more than seventy cases. The patients were more than 18 months of age but otherwise were unselected. Fifty-two cases healed completely by first intention. The functional results provoked spontaneous remarks on the improvement in speech.

Human Infertility—Rowe gives the results of a study of a consecutive series of 100 infertile couples to ascertain so far as possible, the causal or contributory factors. Studies were made on both partners involving a general clinical and laboratory investigation of each supplemented by comprehensive gynecologic and urologic studies on the wife and husband respectively. Although nine of the men and three of the women were adjudged normal, each series shows an incidence of constitutional conditions that could affect fertility actually in excess of the number of patients. In other words, 188 individuals present 213 constitutional disorders of a degree worthy of record. In addition to these, a large number of local conditions were discovered that could also influence the outcome of the mating. Each union in the series presented an average of nearly five significant impediments to fertile mating. Constitutional elements, notably the glandular disorders, are or may be correctable by proper therapeutic measures, a fact most pertinent to the possible solution of the problem. As the author conceives it true fertility of the individual is the summation of the number of functions still maintained at normal levels coupled with a complete absence of all impeding agencies either local or constitutional. Varying degrees of infertility result as one or more of these criteria fail to be realized. Infertility is again a summation of all the subversive agencies in which the total if below a critical boundary or zone, is incompetent to abolish the possibility of fertility but can lower its probability. When two partners of low fertility are united the probability of successful impregnation and pregnancy is lowered still further though each mated with one of high fertility might well participate in a fertile union. Therapy for the condition depends on the correction of all impediments that are correctable and palliation of those in which this represents the sole possibility, thus the index of fertility will be raised and may finally overstep the critical boundary. In that portion of the series in which therapy could be and was applied the outcome has been correction in 50 per cent of the cases. With the development of more effective therapeutic approaches along all indicated lines but more especially in the endocrine field a still larger proportion of success may result.

Estrogenic Substance and Abortion—As the danger of the patients' aborting was to be considered, Shute used two cases in which abortion was desirable from a medical point of view. The results demonstrate that the injection of a potent gonadotropic preparation of pregnancy urine may for a period of a few hours reproduce in the normal blood serum of the patient the effect ascribed to an estrogenic-like substance. If the work on animals is a guide to a proper interpretation of the phenomenon, estrogenic substance is actually produced by follicle ripening, and the effect on the blood serum may be due to this substance. No satisfactory explanation has ever been offered for the failure of the placental villi to penetrate the uterine wall as far as the serosal coat, since they normally are able to erode their way into the myometrium for a considerable distance. It has been taken for granted that there is a certain amount of maternal resistance to such encroachment of the fetal trophoblast throughout every pregnancy. When such resistance is excessive, pregnancy ends prematurely. The placental villi in normal and abnormal pregnancy themselves possess, and possibly secrete, the antagonist to their own erosive agents. Presumably the two tendencies exist during a normal gestation in a progressive equilibrium, and thus the intrusive villi are held in check. But excesses of the resistant factor induce premature termination of pregnancy. In this connection Philipp found estrogenic material principally in the chorionic layer on the fetal side of the placenta. The author finds it difficult to gather together all the different links in the evidence presented but there seems good reason to believe that a substance closely resembling the estrogenic principle, if not actually the substance, is responsible for the appearance in the blood of spontaneously aborting women of a characteristic resistance to the action of the proteolytic ferment trypsin. That it is at least a major factor in the production of abortion has been indicated by extensive work on animals, and the foregoing fact strongly suggests that the same holds true for the human female. It is not improbable that pregnancy is interrupted before term by a premature activity or concentration of the agent or agents responsible for the onset of labor at term, and estrogenic material appears to play a major part in that event.

Amniography—Burke points out that placenta praevia can be diagnosed by amniography. The most characteristic radiographic appearances of the placenta in utero are obtained when the placenta occupies the lower uterine segment. There are a number of factors that materially influence the success of the investigation. Obesity of the patient will defeat the most enthusiastic investigator. As the placenta cannot be seen unless it is viewed in profile more than ordinary care is necessary in conducting the roentgen examination. The amount of amniotic fluid has an important bearing on the result. If there is an excess, the density of the shadow produced by the contrast medium may be insufficient for diagnostic purposes and, unfortunately, there is no rapid method by which the amount of amniotic fluid can be estimated. On the other hand, if the fluid is scanty in amount, uterine puncture may be unsuccessful. This probably is the most serious obstacle in amniography, and in a certain percentage of cases it cannot be performed. In most cases amniography is unnecessary, yet a marginal placenta praevia, which may prove fatal may at an early stage be indistinguishable from a mild accidental hemorrhage. Amniography in all cases of antepartum hemorrhage does not seem practical, nor is it likely to be profitable. The indications for amniography may perhaps be defined by stating that, if in a doubtful case of placenta praevia the history of the case, the physical signs and other important considerations, e.g., age of the patient, parity or desire for a live child, are sufficient to indicate cesarean section as a possible mode of delivery, amniography should be performed. But if delivery will be natural in any case there is little or nothing to be gained by subjecting the patient to the examination. The main value of amniography appears to be as a deciding factor for or against delivery by cesarean section. Therefore there is a definite place for amniography in antepartum investigation. The placenta is actually visualized so that there is no difficulty in deciding whether the placenta praevia is central, marginal or lateral in type. With such accurate information, and having due regard to other circumstances, the mode of delivery should

no longer be in doubt. If the diagnosis proves to be one of central placenta praevia, cesarean section can be undertaken with beneficial results to the child and in full confidence that the mother is not being exposed to unnecessary risk. If lateral placenta praevia is diagnosed, natural delivery can be awaited without undue apprehension for the safety of the mother or the child.

Fate of Antidiuretic Principle of Postpituitary Extracts in Vivo and in Vitro H. Heller and F. F. Urban —p 502

Antidiuretic Principle of Postpituitary Extracts—Heller and Urban find that the antidiuretic hormone of the posterior part of the pituitary is adsorbed by the blood and by tissue suspensions in vitro. If the specific adsorbing capacity of defibrinated blood is 1, then those of muscle, brain, kidney and liver are 2, 25, 8 and 58. The adsorbing capacity of the tissues for the antidiuretic hormone is due to the presence in the tissue of a heat-labile substance that has been extracted. Extracts of liver adsorb more than extracts of kidney. The adsorbing substance can be removed from the extracts by animal charcoal. The blood and the liver contain an enzyme-like substance that destroys the active principle. The rate of destruction in vitro by the blood varies in different species. The quickest destruction occurs in human blood (from 25 to 50 millimicrons per cubic centimeter of blood in from one and one-half to two hours). Cerebrospinal fluid neither adsorbs nor destroys the antidiuretic principle. After injection of large doses of postpituitary extracts the antidiuretic activity of the circulating blood of the rabbit disappears in from twenty to thirty minutes. The disappearance of the same amount of pituitary extract in the corresponding amount of blood in vitro takes from three to four hours. If large quantities of the antidiuretic hormone are injected intravenously into rats part of it is excreted in the urine.

- Measurements of Filter-Passing Particles of Tubercle Bacillus E. M. Fraenkel and R. J. V. Pulvertaft —p 97
Cavitation in Pulmonary Tuberculosis Review of One Hundred Cases R. Y. Keers —p 106
Complement Fixation in Pulmonary Tuberculosis with S and R Antigens G. B. Reed, Christine E. Rice, J. H. Orr and B. G. Gardiner —p 114

Measurements of Filter-Passing Particles of Tubercle Bacillus—Fraenkel and Pulvertaft obtained positive results with the injection of ultrafiltrates from tubercle bacilli (bovine type "Vallee") into guinea-pigs. Infection was obtained by injection into testes or lymph nodes of the neck (Nanni). Ultrafiltrates after filtration retaining other organisms were positive on seven occasions after passing collodion filters with pores of 0.75 micron twice after passing filters with pores of 0.3 micron and on three occasions after passing Chamberland's L candles. From these results the authors conclude that granules and smaller young tubercle bacilli said by Morton Kahn to have a size of from 0.1 to 0.3 micron may have passed through the filters. The filtrate produced mostly localized lesions on the site of the injection, with a few other foci in other organs, spleen or liver. Inoculation of the primary infection produced a generalized tuberculosis in the second generation. Tubercle bacilli could be demonstrated after infection by ultrafiltrates of cultures and by animal inoculation when smears and sections were sometimes negative and histologic changes uncertain. Intracellular acid-fast granules were sometimes present in tuberculous lesions in both gland and spleen. These, however, probably partly consisting of acid-fast mitochondria were also although more rarely present in normal controls.

- Late Infectious Sequels of War Fractures of Limbs Sarroste —p 669
Treatment of Occipital Neuralgia by Alcoholization of Carotid Artery F. K. Kessel —p 739
Attempted Treatment of Impotence by Alcoholization of Spermatic Artery A. Popow —p 749

Treatment of Occipital Neuralgia—If occipital neuralgia by analogy to neuralgia of the trigeminal nerve is a vasomotor neurosis, then, according to Kessel, influencing these vasomotors can cause the disappearance of the pain that accompanies the neuralgia. A review of the anatomy shows that the carotid artery with its internal and external branches is innervated principally by the sympathetic fibers which leave the cervical ganglion and the sympathetic chain and form the external and internal carotid plexus about these vessels. Interrupting these nervous passages by periarterial sympathectomy should prevent the pain caused by angiospasm. In two cases the author succeeded in stopping the pain of occipital neuralgia by interrupting these nerves. The technic consisted in careful dissection of the carotid artery. After denudation of the artery it was surrounded by compresses to preserve the surrounding tissues from the action of the alcohol. Then the walls of the artery were moistened with 80 per cent alcohol by means of small tampons. The walls of the vessel become first white and then dark. The impregnation lasts four or five minutes after which the compresses are removed and the incision is closed. No light is thrown on the etiology of this condition, but the success and ease of the procedure recommend it in cases in which conservative measures prove ineffective.

Treatment of Impotence—Popow discusses male sexual impotence in which the difficulty seems to be a functional disorder of erection. There appear to be several sources of nerve supply which control erection and it has been suggested several times that impregnation of the spermatic artery with various solutions might help the condition. In 1933 and 1934 the author performed thirteen operations on the sympathetic nerves of the spermatic artery by impregnation of the artery with 80 per cent alcohol. The operation, which is painless, is performed under a local anesthetic with 0.5 per cent solution of procaine hydrochloride. The incision is made near the external inguinal ring, the spermatic cord is isolated and the spermatic artery is impregnated with 80 per cent alcohol. As a rule the vas deferens is also impregnated. Care must be used in finding the artery. All but one of the patients were between the ages of 20 and 30 years. The results were good in all instances, but longer periods of observation and a greater number of patients are desirable.

Unilateral Castration by Roentgen Irradiation—Momigliano carried out experiments producing unilateral castration in female rabbits by means of roentgen irradiations on an ovary of the animals. He also made comparisons of the results of this form of unilateral castration with those of surgical unilateral castration in the same animals. The results of the experiments proved that it is possible to cause unilateral castration by roentgen irradiations. No unfavorable effects are produced in the remaining ovary. The modifications produced in the remaining ovary are in relation to the phase of genital development of the animals. In prepubertal female rabbits the ovary develops rapidly reaching a size greater than normal, and there is an early maturation of the follicles. In adult female rabbits in the period of sexual activity, the remaining ovary develops a compensatory hypertrophy which affects especially the interstitial glands. The modifications produced in the remaining ovary by the roentgen irradiations are more favorable than those produced by surgical unilateral castration. It is probable that this is due to the mechanism of action of the roentgen irradiations which permit the products of involution of the irradiated ovary to act as necrohormones and to be absorbed by the remaining ovary.

*Treatment of Empyema of Lung and Pulmonary Fistulas by Intrapleural Irradiations O M Mistal—p 1905

Late Laparotomy in Abdominal Contusions G Marsiglia—p 1910

Treatment of Empyema by Intrapleural Irradiations—Mistal advises direct irradiation of the pleural cavity by ultraviolet rays combined with currents of high frequency in the treatment of empyema and fistulas of the lung and pleura following artificial pneumothorax or complicating pulmonary diseases in which the pleura is opened as a result of a previous operation. The author uses an electrode 20 cm in length and 6 mm in diameter and containing a small amount of mercury, in contact with a neutral gas which causes elevation of the temperature of mercury and hence increases its tension and produces abundant ultraviolet rays. The electrode has also a chamber for ionization and is connected with a diathermy apparatus. The output of rays is constant and even. The instrument should be wrapped with soft and elastic rubber, only its distal end being left uncovered. The back part of the instrument is then inserted up to a fourth of its length into a hard rubber covering through which the instrument is connected with the diathermy current. The patient is placed on the operating table in the same position as for a pneumothorax. Introduction of the electrode in the pleural cavity and irradiations are done under pleuroscopic control. The intensity of the current is carefully and slowly controlled, because of the great sensitivity of the tissues and because direct irradiations are ten times more intense than the indirect ones. The current is regulated by an assistant under the direction of the surgeon. The treatment has a bactericidal and also a biologic osmotic and healing action on the tissues, it sterilizes the pleural cavity, diminishes the empyema until complete disappearance, and heals the pleura and the fistulas.

Pyrethrins in Treatment of Intestinal Parasitosis Preliminary Report J E Camponovo—p 2371

Port of Entry of Tetanus—Bustos discusses the advisability of intervention with wounds that are the port of entry of tetanus, when the disease is already in evolution. The author advises cauterization of the wound in the treatment of tetanus caused by penetrating and small superficial wounds and reports one case. Cauterization is done while the patient is under regional anesthesia by infiltration. In administering anesthesia care should be taken to prevent the transference of bacilli from the wound to its surrounding tissues which may occur if the needle is placed too close to the wound. It is important to precede any operation or treatment of the wound by repeated administrations of large doses of antitetanic serum as any handling of the wound promotes diffusion and generalization of the toxins.

Occult Hemorrhages of Gastro-Intestinal Tract—Hicker, in investigating the method suggested by Bors for the detection of unchanged hemoglobin in the feces found that the

positive outcome of this test does not indicate the presence of unchanged hemoglobin, since he obtained the same results with feces that contained only hematin but no hemoglobin. He found also that under favorable conditions it is possible to detect coproporphyrin (deuteroporphyrin) if only 1 mg is present in 100 Gm of feces, of which 10 Gm is examined according to the method of Schumm. In comparative tests, Boas's modified method proved somewhat less sensitive than Schumm's method. The author describes observations on persons who, after having been kept on a blood-free diet for a longer period, ingested smaller or larger quantities of their own blood or of blood from cattle. He reaches the conclusion that, with the consideration of the sources of error, the demonstration of coproporphyrin in the feces according to Schumm or Boas has diagnostic value. On the basis of the author's observations the pressure of coproporphyrin indicates that hemoglobin or hematin has entered the intestine. In order to exclude the introduction of these substances from the outside, it is necessary to enforce a blood-free diet for some time preceding the test. However, the author stresses that a negative outcome of the coproporphyrin test does not definitely exclude a source of bleeding within the intestinal tract, because after slight hemorrhages coproporphyrin is formed in such small amounts that it is not detectable. He thinks that the hematin tests will as a rule be adequate in cases in which ulcer is suspected. In the case of negative outcome of the hematin test, he considers it advisable to search for coproporphyrin and for increased quantities of protoporphyrin. In cases in which carcinoma is suspected, coproporphyrin should be searched for.

*Meinicke Tuberculosis Reaction and Relations to Tuberculin Sensitivity of Skin K A Lammler—p 291

Peculiar Anaphylactic Pulmonary Disease—Engel calls attention to the so called privet cough, which occurs in China with considerable frequency during May and June. It is popularly termed privet cough because it is believed that it is caused by the pollen of privet (*Ligustrum sinense* and *Ligustrum lucidum*). He describes observations he made on himself as well as on others. The general symptoms are mild, the sputum is of a canary yellow and has a slight metallic taste, there is a severe eosinophilia and roentgenoscopy discloses a pulmonary infiltrate, which however is only temporary and disappears in a comparatively short time. The author thinks that the disorder is an allergic manifestation of the lung in the form of a circumscribed spotted pulmonary edema, which may be elicited by a type of pollen. He recommends the term "allergic vernal edema of the lung." He suggests that the so called laurel fever, which occurs in the New England states, is an analogous disorder. Moreover he thinks that the "succedaneous infiltrates," which Löffler observed in Europe and which have the same roentgenologic aspects as his cases of vernal edema of the lung, may be of the same nature. The vernal edema has differential diagnostic significance because of its roentgenologic similarity with tuberculosis.

Immunization with Dead Tubercle Bacilli—In his experiments Berg used for the immunization of forty-eight guinea pigs human tubercle bacilli that had been killed by high temperatures and of forty-eight others tubercle bacilli that had died in the course of prolonged storage after removal from the culture mediums. The immunization was done in the following manner. With 5 mg of culture material, a suspension was made in 0.5 cc of physiologic solution of sodium chloride and this suspension was injected into the animals three times, at intervals of two weeks. In half of the animals the administration was intraperitoneal and in the other half subcutaneous. Several weeks after the last injection the animals were super-

infected by means of a mixture of three virulent strains. The doses used for superinfection were small. One half of the animals were infected with 0.000001 mg. and the other half with 0.0000002 mg. With the exception of one case, the immunization was a failure. In a small number of animals a slight immunizing effect was noticeable in that the disease process developed more slowly. The author concludes that his studies did not prove that treatment with killed tubercle bacilli produces immunity against tuberculosis.

Use of Disinfectants in Pneumothorax—Muller decided to combine the curative action of the disinfecting substances, which formerly were introduced into the lung by means of inhalation, with pneumothorax therapy. He urged the construction of special pneumothorax apparatus, which permits the introduction of air charged with gaseous medicaments. He atomizes with the following prescription: acriflavine hydrochloride 0.25 Gm., triturated camphor 1 Gm., menthol 1 Gm., thymol 0.25 Gm. and sufficient oil of eucalyptus to make 10 Gm. This quantity is used for one pneumothorax. The most noteworthy effect of this medicothorax is the complete prevention of an exudate, which definitely proves that the pleural space has been sterilized. Another advantage of the medicothorax treatment is the more rapid cure of the tuberculous process. The disappearance of the fever is more rapid than in ordinary pneumothorax treatment.

Meincke Tuberculosis Reaction—Lamml made the Meincke reaction for tuberculosis on 240 persons. Among them were patients with pulmonary and other types of tuberculosis, patients with other disorders and healthy persons. In the course of these investigations the author was able to show that open tuberculosis and particularly the severe cases of this form produce a positive reaction more frequently and also with greater intensity than do the closed forms of pulmonary tuberculosis and the extrapulmonary tuberculosis. He found that clinical manifestations, such as exudative pleurisy, pneumothorax exudate and hematogenous disseminations are more frequent in the cases in which the Meincke reaction was weak. Tests on thirty persons without clinical signs of tuberculosis proved the differential diagnostic significance of the reaction and indicated that the extremely weak positive reactions should not be given a positive interpretation, for only the so-called curvature reaction (accumulation of sediment in the bottom curvature of the test tube) is reliable. Approximately 150 patients were subjected also to the Pirquet test, and its quantitative outcome was compared with the outcome of the Meincke reaction. It was found that, as the Meincke reaction becomes more strongly positive, the Pirquet reaction becomes weaker, that is it appears that they are inversely proportional. In this connection the author suggests that, if the Meincke reaction really indicates the amount of antibodies it would seem that the quantity of antibodies in the blood serum and the tuberculin allergy of the skin (measured by the Pirquet reaction) are in inverse proportion to each other. Thus it appears that allergy and immunity do not run parallel but rather are inversely proportional.

Cause and Treatment of Acute Polymyositis H. Stursberg—p. 17

Withdrawal of Morphine with Ovarian Hormone W. Pettersson—p. 17

Diagnosis of Extra-Uterine Pregnancy—Granzow says that extra-uterine pregnancies present a great variety of clinical pictures. Amenorrhea and genital hemorrhage are not necessarily an indication of extra-uterine pregnancy and the Aschheim-Zondek test is of much less value for the recognition of ectopic pregnancy than for that of intra-uterine pregnancy. To be sure, its positive outcome has proved valuable in a number of cases of ectopic pregnancy but its negative result does not permit the conclusion that there is no extra-uterine pregnancy. The author calls attention to Hegar's sign as an indication of normal pregnancy and says that extra-uterine pregnancy is indi-

cated by a softening of the entire uterus, but particularly in the region of the upper part and of the fundus. He warns against the erroneous interpretation of the enlargement of the ovary by the corpus luteum in some cases of intra-uterine pregnancy, for this manifestation may suggest a tubal pregnancy in sensitive women. This possibility demonstrates the importance of correct palpatory examination, but the author warns against too forceful palpation, since it may cause rupture of the fetal sac. He describes the acute course of a ruptured tubal pregnancy and also the subacute form of extra-uterine pregnancy. Extra-uterine pregnancy may be mistaken for an incomplete abortion and may be subjected to curettage, such a procedure involves great danger in case of ectopic pregnancy and "diagnostic" curettage must be carefully avoided if there is a suspicion of ectopic pregnancy. Adnexitis is another condition that is readily mistaken for ectopic pregnancy. For the differentiation of these two conditions the author recommends diagnostic puncture of the Douglas pouch done only in the hospital. Other erroneous diagnoses that the author encountered in cases in which an ectopic pregnancy was established by a surgical intervention were menorrhagia, ovarian tumor and intra-uterine pregnancy complicated by myoma hemorrhages. He emphasizes that the possibility of an ectopic pregnancy should be more often taken into consideration in the case of obscure abdominal disorders of women.

Is Diphtheria a Septicemic Disorder with Secondary Localization of Pathogenic Organisms on Tonsils? K. W. Clauberg—p. 18

Absence of Basal Joint (or Finger-Thumb) Reflex in Epileptic Attack—Stiefler reviews the earlier literature on the so-called finger-thumb or basal joint reflex, elicited by passive flexion of the basal joint (metacarpophalangeal) of one of the four three-jointed fingers (the third or the fourth is the best) and resulting in an oppositional movement of the first metacarpal, flexion of the basal joint of the thumb and extension of the terminal joint. The thumb remains in this position as long as the finger is held flexed. The author points out that this reflex, which was first described by C. Mayer, is a true joint reflex, a proprioceptive reflex in Sherrington's meaning of that term. It is related clinically and perhaps also biologically to Leris' sign on the forearm. It is elicitable in from 87 to 95 per cent of normal persons, that is, in those who are free from organic disease of the nervous system, but it is absent in young children up to the third year of life. The clinical value of the reflex lies in the fact that it is absent in paralysis and severe paresis in the region of the hand and fingers, resulting from focal disease of the brain. Moreover the reflex is frequently increased in cases of meningitis. The author describes the behavior of this reflex in thirty-six patients with epilepsy. He and Mayer had observed during their early investigations that the absence of the basal joint reflex is characteristic for the fully developed epileptic attack and thus is helpful in differentiating the true epileptic attack from hysterical or simulated attacks provided the reflex is present during the time the patient is free from the epileptic attack. The author found that during the postparoxysmal coma the light reflex of the pupils returns to normal much earlier than the basal joint reflex. He resorted to Foerster's method of artificial production of epileptic attacks by means of hyperventilation and thus was able to observe the basal joint reflex "from beginning to end." In regard to the epileptic mental disturbances, the author says that, in the cases of excitation and distraction in which the pupillary light reflex is abolished the basal joint reflex is either missing or reduced while there are no changes in the abdominal knee and plantar reflexes. From this the author concludes that the behavior of the basal joint reflex deserves especial attention in cases of suspected epileptic mental disturbances. The value

of the basal joint reflex in epilepsy is reduced, however because it is missing or is asymmetrical in almost 10 per cent of epileptic patients (investigations in 350 cases of epilepsy). However, the author thinks that this disadvantage is not nearly as great as the advantages of the reflex and concludes that the basal joint reflex is an important criterion for the completely developed epileptic attack in those cases in which it can be elicited outside the attack.

Question of Exchange Between Blood and Brain G Jorns—p 21

Rickets and the Menarche—Dworzak points out that some diseases of childhood, particularly rickets influence the time of onset of the menstrual function. At his clinic it had been noted that the menstrual function appeared rather late in women who had had rickets when they were children. To obtain data, he compared the time of menarche in 1,200 women who had had rickets and whose skeletal system showed post-rachitic changes with the time of menarche in 1,220 women who had no signs of rickets. Since all the women came from the same territory and from about the same social stratum, climatic, residential and social factors can be disregarded in this material. Tabular and diagrammatic records of the results of the author's studies indicate that the onset of the menstrual function is considerably retarded in rachitic women. He cites other investigators who observed a retarded menarche in women with kyphoscoliosis and he also cites a report about the comparatively high incidence of pelvic anomalies in women in whom the menarche had been late. He reviews animal experiments which demonstrated the development of ovarian and uterine disturbances in animals with experimental rickets. In this connection he points out that it is a widely accepted opinion that rickets is not confined to the skeletal system but involves other systems as well. In view of the animal experiments mentioned, the author considers it probable that the ovaries frequently become impaired in case of rickets.

Treatment of Pneumonia with Quinine-Calcium—Raue treats cases of lobar pneumonia with quinine-calcium (a stable solution of the calcium and quinine salt of levulic acid, containing 0.9 per cent of calcium and 3 per cent of quinine). He commences with the intravenous injection of 10 cc of this solution. In cases of average severity he follows this first injection with daily intramuscular injections and in severe cases with an intravenous injection in the morning and an intramuscular injection in the afternoon, every day until the fever has disappeared. The author found that this treatment produced a favorable effect primarily in cases in which it was begun on the first or second days. In these cases the fever disappeared rapidly, the general condition improved and the local process was rapidly absorbed. The course of the disease was considerably shortened. In patients in whom the quinine calcium treatment was begun between the third and sixth days after the onset the influence on the general condition was likewise favorable but the course was not noticeably shortened. The author considers this mode of treatment especially advantageous for the general practitioner because the majority of patients come under his observation on the first or second day after the appearance of the first symptoms of pneumonia. The quinine calcium treatment should be instituted at once, even if the diagnosis is not yet absolutely certain. If the intravenous injection of quinine calcium should prove difficult, an intramuscular injection can be given. The injection should not be made into the fatty tissue of the gluteus but rather deep into the muscle. If this is done the injection is well tolerated and abscess formation is avoided. Another reason why the quinine-calcium treatment is especially advantageous for the general practitioner is that the serotherapy of pneumonia presents certain difficulties for him.

Radium Treatment of Climacteric Hemorrhages J Molnar—p 664
Injuries Caused by Roentgen Rays G Anasj—p 670

Roentgen Irradiation of Kidneys in Mercury Bichloride Poisoning—Balazs and Czunft state that Stephan was the first to employ roentgen rays for the purpose of counteracting nephritic anuria. Later other investigators tried to find an explanation for the onset of the diuresis from four to eight hours after exposure to roentgen rays. Some authors assumed an irritating action while others ascribed the efficacy of the treatment to the action of the rays on the vessels of the kidney. It was the aim of the authors to investigate (1) whether roentgenotherapy is capable of counteracting an existing anuria and (2) what effect is obtained in cases of milder renal lesions or in oliguria. They emphasize that in estimating the results it is necessary to take account of the fact that in cases of poisoning with mercury bichloride the anuria as well as the oliguria may subside spontaneously. They think that an irradiation can be considered effective only if the favorable effects become manifest within the first twenty-four hours after the irradiation. The authors report the results they obtained with roentgen treatments in eight patients with anuria and in ten patients with oliguria. In some cases they employed larger doses (150 roentgens depth dose) on two successive days or they employed smaller doses (115, 100, 60 or even less roentgens) on two or more successive days, but with the exception of one case the anuria was never counteracted. Even in the one case the effect of roentgenotherapy is not certain, for an improvement to the extent observed has been known to occur in cases in which irradiation has not been employed. In the ten patients with oliguria, only smaller roentgen doses were applied. In these patients the quantity of urine increased after irradiation, but the specific gravity either was reduced or remained the same. The authors reach the conclusion that in case of poisoning with mercury bichloride it is permissible to administer several small doses of roentgen rays as an adjuvant to the usual therapeutic methods but it cannot be expected to counteract the anuria with roentgen rays.

Analgesic Action of Roentgen Rays—Von Meszoly employed roentgen rays for analgesic purposes in 142 patients, thirty-seven of whom discontinued the treatment before completion. Of the remaining 105 patients, ninety-five had neuralgia and ten received roentgen treatment for postoperative pains. Of eleven patients with trigeminal neuralgia, eight were cured and two were considerably improved, while in one patient the pains recurred with their former intensity. Roentgenotherapy was resorted to only in the cases in which no pathologic processes were detectable that is in cases in which the neuralgia was idiopathic. The rays were applied to the lateral portion of the face on a field measuring 10 by 8 cm. The tension was 170 kilovolts and the filter consisted of 0.5 mm of zinc. From 400 to 450 roentgens was administered at one session. The doses were repeated at intervals of six weeks. Whenever the first treatment was not sufficiently successful, from 240 to 300 roentgens was applied to the site of exit of the nerve at the second or third session. The irradiation was usually followed by slight hyperemia, swelling and temporary increase in painfulness, but after that the improvement became evident. The author further reports his observations on sixty-seven patients with sciatica of whom forty-two were cured, eighteen considerably improved and five slightly improved while two were entirely refractory. Considerable improvement was obtained also in seventeen patients with other types of neuralgia (occipital, intercostal, brachial and so on). For the purpose of relieving postoperative pains roentgen rays were employed in four cases of appendectomy, in two cases of tonsillectomy and in four cases after tooth extraction. The pains disappeared after one or two irradiations.

 Sex Ratio in Children's Diseases W Bonell—p 568

Sex Ratio in Children's Diseases—Bonell defines as sex ratio the number of male patients corresponding to 100 female patients. A sex ratio of 100, that is, an equal number of male and female patients, is comparatively rare. During childhood the exposure is practically the same for males and females and the differences in the incidence of children's diseases in boys and girls is primarily due to constitutional and predispositional factors. The author calls attention to the fact that androtropy or gynecotropy may eventually be simulated. This is possible if only the total number of cases of illness is considered, without paying attention to the ratio between males and females in the group of population that is under consideration. The author shows that there are some diseases the sex ratio of which undergoes apparent or real changes in that, for instance, their androtropism changes to gynecotropism that is, they are poikilotropic disorders. In considering the total morbidity, the author reviews an American and a Russian report. These reports indicate that during the first quinquennium of life, but particularly during the first year, the morbidity is greater in boys than in girls. In analyzing the figures the author found that this greater morbidity in boys changes to a greater morbidity in girls in America during the sixth year of life and in Russia during the eighth year of life. The author points out that most of the developmental anomalies (sitis inversus, left-handedness, hernias, Hirschsprung's disease, congenital cardiac defects and so on) show a decided androtropism. In analyzing the acute infectious diseases, he admits that a strict differentiation into androtropic and gynecotropic infections is difficult; however, there is some evidence that in boys there is a predominance of the infections that have a neurotropic tendency whereas in girls there seems to be a predominance of those which have a dermatotropic tendency. Whooping cough is decidedly gynecotropic. Regarding rickets, the opinions differ considerably, some considering it androtropic and others gynecotropic. The manifestations of exudative diathesis are decidedly androtropic. The author also considers the sex ratio of the blood diseases and of several other disorders.

 Observations in Porphyria K Hoesch and C Carrie—p 214

Pernicious Anemia and Splenomegalic Polycythemia—Barath and Fulop after calling attention to the importance of Castle's intrinsic factor in pernicious anemia, point out that Morris and also Hitzenger have suggested that an excess of Castle's intrinsic factor might play a part in polycythemic conditions. However, although it is highly probable that Castle's intrinsic factor is increased in patients with polycythemia there is as yet no definite clinical proof. Accordingly the authors decided to investigate the effect of the gastric juice of patients with polycythemia on the blood picture of pernicious anemia. They had under observation three patients with splenomegalic polycythemia who had erythrocyte values between seven and eight millions. The examination of the gastric function disclosed severe hyperacidity. In order to obtain their gastric juice for the treatment of five patients with pernicious anemia the polycythemia patients were given 200 Gm of beef and then a subcutaneous histamine injection of 0.5 mg. After that the gastric juice was withdrawn for from three to five hours the usual yield being from 500 to 600 cc. This gastric juice was filtered and neutralized and then administered rectally

to the patients with pernicious anemia in quantities of from 200 to 300 cc. These rectal administrations were repeated for several days until a total of from 800 to 1,400 cc had been reached. The withdrawal of the gastric juice from the polycythemia patients was continued for several weeks, so that there always was a supply. In five cases of pernicious anemia the erythrocyte values increased rapidly, while in a sixth case, which had been refractory to other therapeutic measures, only a slight increase in erythrocytes was obtained. The authors proved the efficacy of the gastric juice of polycythemia patients in the reticulocytic test on rats (K Singer's method). On the basis of their observations, they reach the conclusion that pernicious anemia and splenomegalic polycythemia are opposites. In the first condition there is a deficiency of the hematopoietic gastric substance, while in the second condition there is an excessive production of this substance. The withdrawal of large quantities of gastric juice following feeding with meat and subcutaneous injection of histamine has a favorable effect on polycythemia provided the treatment is continued for a long period. The authors concede that this treatment of polycythemia will probably not have a lasting effect.

Influence of Bath on Venous Pressure—According to Kruger and Budelmann, it has been determined that the venous pressure increases during bathing. They think that this increase is a result of the hydrostatic pressure. In this connection they point out that Schott determined that the intrapleural pressure increases under the influence of the hydrostatic pressure, and they maintain that this is a result of the compression of the thorax by the water. They decided to investigate to what extent this increase of the intrapleural pressure will explain the increase of the pressure in the extrathoracic veins and also whether this change in the intrapleural pressure during bathing may influence the venous backflow. They found that the hydrostatic pressure of the bath effects an increase in the intrapleural pressure. The volume of the intrapleural increase in pressure is determined by the height of the water column that stands above the thorax during bathing. The pressure in the intrathoracic veins (superior vena cava) and in the extrathoracic veins (jugular vein) increases together with the intrapleural pressure. The extent of the pressure changes in these veins is dependent on that of the intrapleural pressure change. The authors assume that the increased pressure in the extrathoracic veins (to the extent that they are within the region of the superior vena cava) is entirely determined by the intrapleural pressure changes and is not a result of the backflow. The intrapleural pressure increase during bathing, in case of equal hydrostatic pressure, is greater when there is no discharge of air from the lung.

 Clinical Diagnosis of Congenital Atresia of Biliary Tracts P M Vitina and F A Revis—p 865
 Symptoms of Primary Lymphogranuloma of Mediastinum P P Litova—p 867

Treatment of Leprosy—According to Rozental, this treatment was introduced by Gordon A Ryrie and consists of intravenous injections of aniline dyes that exhibit a selective affinity for the leprosy lesions. The immediate effect of this chemotherapy is an intense bluish discoloration of the leprosy lesions. Lesions containing bacilli are discolored more than those containing none or a few. The more intensely discolored lesions undergo a more rapid involution. Patients complain of an intense itching of their leprosy lesions on the same or the following day after injection. There may be a sense of intoxication, general malaise, dryness of the mouth and mild sweating. Because of varied response the treatment must be strictly individualized. The author treated thirty-one patients in all stages of leprosy, using a 0.5 per cent solution of brilliant green or a 1 per cent solution of methylene blue. The dose ranged from 5 to 30 cc and was repeated every five or six days. Seven patients were rendered bacillus negative within two months, while the rest showed a marked diminution in the number of the bacilli and an improvement in the ulcerative lesions. The author did not observe any untoward effect on the kidneys.

FUNCTION OF THE HOSPITAL IN THE TRAINING OF INTERNS AND RESIDENTS

J A CURRAN, MD

Executive Secretary New York Committee on the Study of
Hospital Internships and Residencies

NEW YORK

Modern medical education requires a comprehensive program covering the entire professional life of the physician. To be effective, each step must be planned for the years as medical student, as resident staff member, and in practice. Viewed in this light, the internship and residency seem pivotal in the whole scheme of things. Certainly to an extent equal to the four years in medical school, the hospital service plays a vital part in conditioning the young physician in methods of approach to his patient's problem, in modes of treatment and in general ideals of practice.

It has become increasingly apparent to medical educators, however, that the training furnished house staffs is often not as effective as it might be. Disquieting reports drift back to the medical alma mater, dissatisfactions are voiced by hospital intern committees with the type of preparation their candidates have received, and intern groups themselves have become increasingly conscious of essential elements missing from their training.

The whole question is one of such complexity, with so many intricate factors woven into its fabric, that it has been extremely difficult to know where to make a beginning. Medical colleges have repeatedly carried out searching self criticism of their methods and accomplishments, which have resulted in great improvement in the quality of their graduates. It is logical, therefore, that the next step should be a similar critical analysis of medical education as it is applied during hospital residence. During this period, the value of college teaching is put to the test and it is needful for medical faculties to extend their interest and knowledge definitely into the intern years.

The Council on Medical Education and Hospitals has presented the problem squarely, has made hospitals realize that minimum standards exist and has been a far-reaching stimulus for improvement.

The five boroughs of New York City present peculiar advantages for initiating a cooperative medical college-hospital survey. In this compact and densely populated area are found seventy-nine general and special hospitals approved by the American Medical Association at the present time. Their house staffs total more than 1,600 individuals representing approximately one

sixth of the number in the United States. When additional groups serving in unapproved hospitals and suburban areas are included, the total will approach 2,000. All types of experience are among the opportunities offered. As a result of the many openings available, graduates of about 90 per cent of American medical colleges, as well as large numbers of Canadian and European schools, are represented. A preliminary study of one half of the group revealed the fact that 55 per cent were graduates of other than the five medical colleges of New York City.

For some years the Committee on Medical Education of the New York Academy of Medicine and the deans of Columbia, Cornell, Long Island, New York Homeopathic and New York University medical colleges have been carrying on independent studies of internships and residencies in local hospitals. Finally in 1934 a joint committee was organized and through a substantial grant from the Commonwealth Fund a two year project for careful examination of every hospital in the metropolitan area was made possible. This plan included visits to neighboring medical centers also. The investigation is still in progress and its conclusions will not be completely available until some time after July 1 of this year. Needless to say, the work would not be possible without the cordial cooperation of the hospitals involved, and this has been freely given. They have also furnished representatives for service on the subcommittees dealing with different phases of the general problem.

The results of the survey are made available to each hospital for its information and guidance. These informal follow-up reports have resulted in frequent beneficial changes in the house staff situation.

OBJECTIVES OF COMMITTEE

To sum up the plans of the committee in general terms its objectives may be outlined as follows:

1. A systematic and thorough study of internship and residency training as applied in a large, representative area.
2. Through information thus received, to clarify our minds as to what place the house staff experience should have in the general plan of medical education.
3. To arrive at some evaluation of the methods now in use, designed to qualify the physician for different types of practice.
4. To supply educational institutions and hospitals with adequate data vital to their individual needs.
5. To act as a clearing house of information through which the schools and hospitals may benefit from the experience of others.

The knowledge obtained in one and a half years of effort makes us hopeful that these objectives are obtainable and that a great deal of constructive work will be done. While incomplete information makes definitive statements not yet possible, it is my purpose in this paper to discuss some of the difficulties encountered and feasible remedies.

PROGRESS OF INTERN

Perhaps the simplest method of approach is to chart the progress of the intern from the beginning of his service, asking ourselves a series of questions along qualitative lines

1 Is introduction to medical duties and responsibilities systematically provided?

2 On beginning his duties in the emergency room and on the ambulance, is instruction given in minor surgical technics and first aid?

3 Is attention paid to adequate grounding in ward technics as dressings, spinal punctures, clyses, venipunctures and examinations of body orifices, or must the intern learn them by practicing on the patient?

4 Are nursing procedures outlined and demonstrated to the intern, so he may appreciate and supervise them properly?

5 Is he introduced to the operating and delivery room with the same care as is a pupil nurse?

6 At the bedside, are his observations given serious attention at the time of regular rounds?

7 Is an outline for keeping medical records taught?

8 Is there a tradition for the intern to summarize his observations and present them effectively both at rounds and at the regular departmental conferences?

9 Are laboratory tests carried out as meticulously as in medical school and are they performed in connection with study of an individual patient?

10 Is reading of medical literature stimulated?

11 Does an appreciation exist of the patient as an individual and of the importance of social, psychologic and spiritual factors in health and disease?

12 Do the members of the attending staff comprehend their responsibilities as preceptors and take a personal interest in the objectives of each intern entrusted to their care?

13 Is a method for systematic appraisal of the intern's work carried out?

Another mode of approach is to trace the contact of the intern with the patient throughout the latter's hospital experience. Osler once said that the only way to learn medicine was from a textbook but that the only real textbooks were individual patients. Logically, if the intern is to become familiar with the natural history of disease he must study the patient during the preliminary period in the dispensary or emergency room, while the diagnosis is being established and therapy applied in the hospital and then the evaluation of results at follow up.

Finally, it is most desirable that an appraisal be made in terms of objectives. Is the group being trained to meet the needs to be encountered in practice?

DIFFICULTIES AND SUGGESTIONS FOR MEETING THEM

It is not possible within the limits of this paper to discuss all these problems, nor is our committee yet prepared to give definite answers. However, certain major difficulties may be indicated and probable lines along which solution may be sought.

I will take up the first question asked, that of introduction of the intern to his work. Dr Wyckoff, in his discussion mentioned the internship as an experience involving increasing responsibility. To be effective this must be definitely planned for.

Systematic outlining of the intern's duties and supervision of his introduction to them has been provided in only a few hospitals. Frequently this function has been left to the casual attention of a resident, an older intern, the charge nurse or a member of the attending staff, as problems arise. During the first few months of his service, the intern is eager for instruction, has not become fixed in bad habits and can be molded to sustain high standards. It is the most critical period

of the entire house staff experience and probably of the whole plan of medical education. Besides his urgent need of learning to carry out techniques carefully and skilfully he needs active guidance and appreciation from his elders in his efforts at diagnostic studies. Too often a painstakingly recorded history and physical examination are ignored, and a bad example of snap judgment as to diagnosis and treatment is given by a hurried member of the visiting staff. Very frequently no attempt has been made to define and outline the content of acceptable case records, and to the record librarian has been delegated the impossible task of editing these reports. Such irregularity makes utilization and checking by the attending staff difficult and it encourages careless habits and short cuts. Conversely, where uniformity exists there is increased interest in the interns' work, habits of exact observation are encouraged and there is stimulation for clinical investigation. While the task is a tedious one the only first class records are seen where the chief of the service takes personal responsibility for enforcing standards. In the majority of instances the interns are left too much to their own devices under the comfortable assumption that if sufficient initiative and interest are displayed adequate instruction will be given.

If standards are to be set the proportion of interns to patients must be properly adjusted. As Dr Zook has so ably stated there is need of proper balance of qualitative and quantitative criteria. The usual method of estimating case load by calculating the ratio of house staff to beds is far from accurate in revealing the actual picture. Great variation exists in bed occupancy. The presence or the absence of an ambulance service makes a vast difference in the number of interns who are available for work in the hospitals. The ratio for the entire group does not portray the difference between services.

If future needs in practice are considered it is necessary to visualize what conditions our graduates will be asked to face. Since all may presumably enter general practice, such needs must be first considered. According to the Final Report of the Commission on Medical Education, the ten most frequent demands on the general practitioner are:

- 1 Infections of the upper respiratory tract
- 2 General medical diseases
- 3 Minor surgery
- 4 Gastro intestinal disorders
- 5 Obstetrics
- 6 Venereal diseases
- 7 Throat infections
- 8 Pneumonia
- 9 Contagious diseases
- 10 Ear, nose and sinus infections

Even brief consideration reveals why so many interns are ill fitted to enter their careers. Few have any experience in dealing with contagious diseases or venereal problems. Facility may have been acquired in tonsillectomy but little skill obtained in the diagnosis and care of otitis media, sinusitis and various throat infections. Pneumonia may be well handled but without much idea of what to do for the common cold. A vast amount of time is usually spent in assisting with major surgery but little instruction is given in minor surgical technique. Some hospitals offer no obstetrics at all and many an insufficient amount. Physical therapy as applied in general practice is a neglected field. There is a pressing need for a shift from almost complete emphasis on the curative and technical aspects

of medicine to include training in the widening field of preventive medicine and public health.

Too often our hospitals move and have their being in a small cosmos of their own. Objectives for the house staff do not reach beyond the limits of the hospital walls. The cloistered existence of the intern gives him little opportunity to select for himself the training that will best fit him to serve the community.

Practical suggestions for meeting hospital deficiencies must be guided by the abilities and capacities of each institution to carry them out. Both city and voluntary hospitals are struggling with serious financial limitations. Changes involving additional expenditure can be undertaken only after consideration of ways and means. In private hospitals it is desirable to have at least 50 per cent of the patients in the general service if teaching standards are to be upheld. Reginald Fitz has pointed out that in Massachusetts the quality of the house staff group in voluntary hospitals was usually directly proportional to the amount of endowment.

A voluntary attending staff cannot be expected to spend additional hours in teaching if its members already are barely making a living.

The solution, therefore, appears to be in organization and systematization of present resources and facilities. A few illustrations to show my meaning will be given.

1 The preparation of manuals by some of our better hospitals specifying the basic essentials for adequate care of the patient could be extended to others with great benefit, particularly those in which the attending staff rotates on duty. Such a manual has been in use for several years in the Third Medical Division of Bellevue Hospital. It is of especial value in that it provides training for the staff in both general and special medical methods. Being frequently revised, its educational influence is profound. The surgical service of the Peter Bent Brigham Hospital in Boston has an admirable booklet, both in spirit of conception and in content. It serves as joint guidance for both the medical and nursing staffs. Books of nursing procedures are found in the wards of all our hospitals, designed to anticipate the doctor's needs. A curious omission is that of a complementary book to teach the interns how to use the nursing provided.

2 In the January issue of *Hospitals* is an article by Dr Emanuel Giddings of the Morrisania Hospital describing experiences in teaching interns nursing procedures. Participation is given in such practical and homely matters as how to make a patient comfortable in bed, how to prepare and apply a mustard paste and how to make up and give various types of enemas.

3 Regular, separate departmental conferences are a basic essential. The residents and interns take an active part in preparation for these meetings and receive some of their best education as they participate. An unfortunate tendency has been to hold one conference for the entire hospital with crowding of the house staff into the background. The attempt to cover statistics, mortalities, morbidities, interesting cases and pathologic material for all services in a single hour's time is a physical impossibility.

4 If the intern is to follow his patient throughout the course of his illness a definite provision must be made for regular assignment to the dispensary. There is a growing tendency to set up a half or full time schedule over a period of weeks or months. Supervision is furnished in part by the senior members of the attending staff. There is no reason why all interns may not regularly have their place at follow up.

The training possible in the various special clinics of the outpatient department is of utmost practical value and cannot be duplicated in the wards.

5 The reason why so many hospitals lack a satisfactory library has been their inability to finance a full time librarian. An ideal arrangement, when architecturally possible, has been to place the reference and record libraries in connecting rooms or suites, with the record librarian in charge of both. Another plan has been to place a full time employee, as the anesthetist or the operating room secretary, in control. Both methods have been tried and have been successful. With this basic essential, books and periodicals have been freely provided by members of the staff and their friends. Weekly journal clubs can then be organized which are of far-reaching influence on reading habits.

The lack of adequate libraries in some hospitals in the past has been the chief reason for provincialism, unscholarly habits and unprogressiveness.

Nothing has been said up to this point of formal lectures. This has been intentionally left to the last. Too often, when intern training has been considered, the first impulse has been to plan a series of lectures. Very frequently these have failed of their purpose. An arbitrarily arranged curriculum is about as interesting as the routine perusal of a textbook. In hospitals without medical school teaching services, the best substitute seen has been the organization of a weekly seminar by the interns themselves. The speakers invited and the topics discussed are interesting to the interns, as they deal with problems encountered in the hospital.

In conclusion, I would venture the assertion that our hospitals must face the need of a more adequate basic internship. Judging from the thousands of young men who come to New York from all parts of the United States and Canada for additional hospital training, it would appear that the one year rotating internship most of them have obtained is insufficient for their needs. As already mentioned, more than half of the house staff group is drawn from sources outside the city. It will perhaps be surprising to some that a preliminary poll of our metropolitan intern population indicates a desire among most of them for a three year house staff experience. Nor is this wish based on the expectation that such a length of service will turn them out as qualified specialists. It will merely fit them for the needs of modern general practice with extra training in one field.

The function of the resident or fellow is manifold. He furnishes continuity of program in upholding standards, supplements necessary instruction of interns, and carries out special studies. His progress toward specialism depends on the number of years spent.

The criteria formulated by our national boards of specialization have already had a marked effect not only in lengthening and improving existing residencies and fellowships but in stimulating the creation of new ones.

It appears that the method of preceptorial training in a private office or by progression on the special staffs of hospitals is not going to satisfy the needs of the future.

To give the house staff experience its proper place in medical education, a larger number of attending staff members with a teaching interest must be provided. Osler once remarked that "a good teacher was a man who could think, could express himself, and had well developed technique." To this he added the essential qualities of "enthusiasm, that deep love of a subject that desire to teach and extend it without which all

instruction becomes cold and lifeless, and, secondly, a full and personal knowledge of the branch taught, not a second-hand information derived from books."

Such an ideal cannot be attained without thorough and intimate study of every patient encountered. If each attending staff member will set for himself the goal of thorough supervision of his interns in the carrying out of essential case studies, he will reap the reward of a profound understanding of medicine. Perhaps the best way to understand a subject is to teach it. In the last analysis, by setting high standards for our interns and living up to them ourselves, the fundamentals of an adequate teaching program are achieved.

The spirit of progress is not evolved from a consideration of abstract ideas, but from living, moving forces, swelling from beneath the surface, which give birth to new methods and courses of action, impelled by the necessity of meeting the growing needs of mankind.

It is imperative that medical groups throughout the country intensively study their own local problems. The zeal and dynamic for their solution must come from within each hospital community. Only thus may the American Medical Association be given proper support in its nation-wide task.

INDIVIDUALIZATION IN THE PRESCRIPTIONS FOR NURSING CARE OF THE PSYCHIATRIC PATIENT

WILLIAM C. MENNINGER, M.D.

TOPEKA, KAN.

It is my purpose in this paper to describe the method that my associates and I have evolved to meet the problem of individualizing the prescriptions for nursing care of the psychiatric patient in the hospital. Physicians directing the recovery processes of the mentally sick are constantly confronted with the problem of controlling and organizing the patient's time during the intervals between personal contacts. With an average of fifty patients, under the supervision of ten full time physicians, it has been possible at this clinic for a physician to spend between thirty and sixty minutes daily with each patient. We consider it to be our opportunity as well as responsibility, however, to prescribe and supervise the management of the patient during the remaining twenty-three hours of each day, necessarily through the aid of therapeutic assistants, i. e., nurses and special therapists.

The therapeutic conferences with the physician may color the patient's reactions and behavior, but the effect of the physician's work may be neutralized or even counteracted unless a prescribed management and a program of activities can be effectively carried out by these nurses and therapists, and their work closely supervised and repeatedly checked.

The present plan has evolved gradually over a period of several years and can be roughly divided into three phases. We first found it necessary to develop an organization of assistants, all of whom were therapists of a special sort and not merely bed makers or keepers of the keys. It was necessary not only to use extreme care in selecting the personnel but also to teach them the fundamentals of psychiatry, that we might thus

From the Menninger Clinic
Read before the Central Neuropsychiatric Association, Topeka, Kan.
Oct. 25, 1935.

inculcate in them a psychiatric point of view. It became essential to give them some general understanding of psychodynamics, in addition to the outlines of descriptive psychiatry, and to teach them the important concepts of psychiatric nursing implied in such familiar phrases as "sympathetic understanding," "eternal vigilance" and "patient perseverance." Only through special training could we help them attain an objective, nonemotional attitude and impersonal behavior.

The second step in the evolution of our method was to develop a system by which we might convey to the carefully selected, psychiatrically trained group of assistants an individual prescription for each patient of the special activities which this corps of assistants might lead or direct.

The third step was to work out a plan to coordinate these prescribed activities, to supervise their execution and to measure their effectiveness as therapeutic measures.

SELECTION AND TRAINING OF PERSONNEL

Our choice of personnel is based initially on the individual's intelligence, his interest in the field, and the stability of his personality, but even though he is interviewed by several members of our staff it is not always possible to judge these factors accurately without a practical trial. The requirement that our nurses be graduates of an accredited general hospital training school and that our therapists and male attendants have some college training usually insures an adequate intelligence.

Each individual is requested to furnish an explanation of his desire to enter the field of psychiatry. We have found that it is impossible to carry out an effective therapeutic program with attendants who, even though intelligent, are working merely to make a livelihood and have no deeper interest in their jobs, or with persons who go into psychiatric work in an attempt to solve their own neurotic difficulties. The stability of the personality is far more important than its particular makeup. We have found it expedient to have various types of personality included in our personnel: e.g., the maternal nurse may be especially successful in the management of an infantile personality, through her soothing solicitousness, her comforting voice and her maternal attitude of protection. A schizoid individual may succeed in obtaining the cooperation of schizophrenic patients in many instances in which a more extroverted nurse fails. The firm and domineering type of personality may be of special advantage with the "spoiled child" type of patient. Regardless of the type of personality, the character trait of stability, which may be evaluated roughly from a social history giving facts about the home situation, the scholastic record and vocational experience, contributes largely to success in psychiatric therapy.

We must depend on our personnel to create a friendly and secure environment. We expect a nurse to be a confidential friend of the patient and a companion in recreational and occupational activities. She must be a diplomat in handling actual difficulties that arise concerning treatment and privileges. Finally, she must be the doctor's chief observer of the patient's behavior and at the same time be capable of charting it intelligently and accurately. But one can expect none of these functions on the basis merely of her native intelligence, her enthusiasm and her emotional stability.

To enable the nurse to carry out this difficult assignment of functions she must have psychiatric knowledge. She must have a functional and not merely a

theoretical understanding of psychodynamics. She must know not only the methods used in the therapeutic management of each type of mental illness but the reasons for them. It is necessary to teach her the various difficulties she may encounter and their solution and the rationale. She must be taught that the companionship or friendship prescribed for the mental patient can and must be scientifically controlled. She has to be taught what to observe in the patient and how to record it. Probably the most important lesson in her training is to become objective and nonemotional and yet at the same time remain sympathetic, friendly and understanding in her relationships to patients.

In our experience we rarely have found an individual who was able to carry out these functions entirely to our satisfaction on the basis of previous training. For this reason we established a training school with a prescribed course of three trimesters running continuously. There is a wide variation in the schools of thought and actual practice in psychiatry, and it is important that our personnel understand our attitude and practice. For this reason, each senior member of the medical staff gives lectures in this training school as do also the heads of the occupational, recreational and physical therapy departments, as well as the nursing instructress. Regardless of previous training, each new nurse and therapist, and even the secretarial help, take this didactic work.

The work of the first trimester is devoted to a presentation of fundamentals. The course in psychiatry is largely devoted to psychodynamics, including mental mechanisms and types of personality. Psychiatric nursing covers the application of these theories to practice in such fundamentals as precautionary methods, the explanation and interpretation of the physician's prescriptions, and routine procedures. A course in neurology is given to orient further the nurse in its relation to psychiatry, as well as for its practical application in the neurologic syndromes frequently seen.

In occupational therapy and physical therapy the nurse is given both theory and practice. In recreational therapy she learns not only theory but also a large variety of recreational activities. The first three months' work includes a total of 120 hours of lecture and recitation work, which amounts to nine hours of classroom work each week.

The work in the second trimester is planned to include a dynamic as well as a descriptive study of the more common mental illnesses and, in addition, the principles of clinical psychology and child guidance. Each student is required to make case studies and to write book reviews. The work includes a total of sixty-six hours of lecture, an average of five hours a week.

By the third trimester it is assumed that the nurse is oriented sufficiently well in psychiatry to profit from a course in psychoanalytic theory. We regard this subject as of paramount importance in part because many patients in the hospital are under psychoanalytic treatment and also because our actual practice as far as possible is based on an analytic understanding of the patient's problems. In addition, the nurse is given the opportunity to write a research thesis to encourage the expression of her own originality, as well as to increase her familiarity with the literature and the use of the library. Other lectures deal with ward management and special psychiatric hospital problems. This course in psychiatric nursing has been approved by the State Board of Nurses' Registration and is accepted by Washburn College for ten hours of college credit.

THE PHYSICIAN'S PRESCRIPTIONS

With all this training the nurse or therapist is still not informed with regard to the program of treatment for the individual patient until the physician has written his prescriptions. We have found it necessary in making prescriptions to include not only some information about the patient himself and suggestions for special activities but also the more subtle recommenda-

That the explanation of our order sheet may be more understandable I shall illustrate its application by the case history of a patient. We obtained the following history from the patient and his brother just prior to his admission to the hospital. He was an intelligent business man 42 years of age, whose chief complaint was an assortment of hypochondriac ideas, associated with anxiety and compulsive behavior, beginning

tions of the attitude the nurse should take toward the patient's complaints and the manner in which she should make her requests of the patient. Our admission orders comprise three full sheets of detailed instructions (shown in the accompanying tabulation). In addition to giving a tentative diagnostic grouping outstanding symptoms occupation and family situation the orders cover twelve special categories of prescribed attitudes and activities. In writing the prescriptions it is necessary only to underline on these order sheets the desired attitude or activity.

approximately 1 year prior to consulting us. At the age of 9 years he had an anxiety attack of some months' duration because he was afraid he might die of scarlet fever which was then affecting another member of the household. At the age of 21 following a minor abrasion on his thigh he feared that he might lose his leg. At the age of 29 he had a tonsillectomy, which was associated with a great fear of death. At the age of 39 he developed a profound emotional reaction at the time of a gallbladder operation. At the age of 41, a friend died of angina pectoris and he developed a severe car-

diophobia. His present illness began with anxiety over paresthesia in his hands but rapidly increased to include concern about his heart and his general physical health. He had himself examined in several clinics and put himself through the gamut of every type of clinical and laboratory investigation. Physical and laboratory examinations from these clinics were reported to be entirely negative. He became depressed and tearful, took his pulse and temperature regularly, and developed an intractable insomnia. From his brother's point of view he had always been an extremely self-centered individual. He had always dominated the home and had been pleasantly unkind and inconsiderate of his wife and their four children. One month prior to the onset of his present illness his son joined him in his business.

It will be noted from the tabulation of the order sheet that our orders are divided into twelve sections and individualization in prescribing is possible because of an extensive variation of possibilities in each section. Based on the historical data the prescriptions for our patient were written and I will discuss his specific orders section by section and thus illustrate the application of this plan.

In the first section, which sets forth the privileges permitted the patient, he was given "restricted privileges." Because he had come voluntarily it was felt unwise to give him "no privileges," but because of the anxiety present it was felt equally unwise to give him either freedom of the grounds or permission to go to the city alone. In addition, the order indicated to the nurse that she was to take "special precautions," which is our code language for specific precautions against suicide. While the patient's history indicated no suicidal attempt, it is our policy to take such precautions in each instance in which the history indicates or the patient himself exhibits depression or anxiety.

The second section is devoted to prescribing the attitudes to be adopted by the nurse toward the patient. In the instance of our patient the nurse was instructed to watch him closely, primarily because of a history of indecision and unexpected behavior. She was instructed to be reassuring in her manner and at the same time firm since with anxiety reassurance and firmness are always in order as a necessary support to the weakened and indecisive ego. She was instructed to be slightly indulgent in the interpretation of his privileges, since he had come voluntarily and too rigid a regimen of supervision in this type of individual is always provocative of further rebellion, without therapeutic benefit. The nurse was instructed to refer his questions regarding restrictions as well as any major requests to the physician, this order was indicated because of his superior intelligence and the neurotic rather than psychotic nature of his illness. She was ordered to make requests of him initially in a matter of fact manner, and if necessary to persist in them but without demanding or humoring, or any other method that it is possible to indicate in the orders. Invitations to participate in recreational and other therapeutic activities were to be extended in a matter of fact manner. Complaints that he made were to be listened to in a sympathetic manner, but without comment since it was expected that he would make many complaints stimulated by his fears about himself.

It can be seen from these order sheets that the possible variation in these initial attitudes is very large, and each of the terms used is defined and presented with an explanation and discussion in the course in

psychiatric nursing, and further reviewed in therapeutic seminars for the nursing supervisors and therapists. Consequently, they are actually only abbreviations for an elaborate concept and actually represent a system of management.

In the third section of the orders devoted to practical points of management of the patient in the hospital, this patient was assigned a daily task, to be selected by the nurse, with the aim of immediately giving him a minor responsibility. In addition, it was indicated that he might shave himself under supervision, an order which is ordinarily something of a contradiction to suicidal precautions. Our patients are permitted to shave only with safety razors and in this instance it was felt that the patient's hearty cooperation would be jeopardized by forcing him to go to the barber shop in the hospital to submit to being shaved. The nurse was further instructed to encourage his socialization which indicated to her that she was to introduce him to each of the other guests and to encourage him to sit in the living room instead of keeping him in his room alone, or leaving him to his own inclinations. There was much evidence in our patient's history of underlying hostile attitudes and on this basis the therapeutic aim indicated on the order sheet was "to afford an outlet for his aggressions." This was done by allowing him to express himself freely, which he did in his verbal attacks on the nurses and in his protests against any sort of restriction despite his repeated affirmations of cooperation.

In physical therapy the patient was ordered to have a tonic type of treatment including ultraviolet rays, massage, and salt glows, and the therapist was instructed to invite and if necessary to urge his compliance. We have found it desirable to prescribe physical therapy for nearly every patient, in part for its physiologic and in part for its psychologic effect. We prefer the sedative effect of continuous baths and wet cold sheet packs to excessive chemical sedation, and undoubtedly there are beneficial tonic and eliminative effects from the other physical therapy measures used. Our case serves as an excellent illustration of the importance of the psychologic effects, namely, the personal attention and physical manipulation which we believe were probably more beneficial than the physiologic effects, judging from his enthusiastic comments and overvaluation of the procedure.

In bibliotherapy the initial order for our patient called only for the daily newspaper. An early revision however added mental hygiene literature. Following the early psychotherapeutic conferences with the physician it was believed that his understanding of the unconscious motivation of his symptoms might be hastened if the therapeutic interviews were supplemented with reading matter dealing with mental health. We feel that mental hygiene literature is rarely helpful to sanatorium patients. On the other hand, we attempt to use reading as a treatment for every patient, though all reading matter must be approved by the physician before it is given to the patient, even though the latter has requested it. In general, biography, history and travel books have proved most satisfactory, probably because of the opportunity for innocuous identification by the patient.

No order was made for our patient in the field of educational therapy. In any individual showing as much anxiety as he did the possibility for application and concentration to any type of study is so slight that it bids fair to fail. On the other hand, our order sheets

permit the physician to recommend to the educational director the trial of a variety of subjects, the most popular being ballroom dancing, interior decorating, music appreciation, sketching, shorthand and type-writing. Through the opportunity afforded by university extension courses and an affiliation with the local college, the patient may have almost any type of educational work that seems to promise therapeutic value.

In recreational therapy our patient was to be invited and if necessary urged to participate in indoor and outdoor games as well as going horseback riding and attending the dances, picnics, moving picture shows and teas. The object of this prescription was to encourage under supervision the extension of his interests from his hypochondriac delusions to these outside activities. Golf and playing ball were especially indicated as a specific outlet for his aggressions in a socially acceptable manner. Following a satisfactory game of golf, his antagonism toward his environment as well as his concern about himself was always much lessened. In this section the physician also prescribes the number of hours to be spent in this department, and he may indicate whether the recreation is to be carried out only with the therapist or in a group. In addition to giving him an outlet for aggressions on objects, the patient's recreation should make reality more pleasant. It also affords an opportunity for resocialization. In the case under discussion it was primarily through the social activities, the teas, parties and dances, that he was given the opportunity of regaining his confidence in the presence of others. Before he left the hospital he had twice presided at the patients' forum, once giving a motion picture show of some of his own pictures of a trip in Europe and later making a talk on the political situation in his state and leading the subsequent discussion.

The next two departments, project work and occupational therapy, are closely related. By project work we refer to outdoor physical labor, and by occupational therapy to various indoor handicrafts. In this instance the therapist was instructed to place the patient immediately on construction work, graded both as to complexity and as to the amount of physical effort required. In occupational therapy he was to go to the shop to work for a period of two hours each day on furniture construction, with an opportunity to develop a hobby and work out a project requiring intricacy, skill and concentration.

It is our thesis throughout that the physician should prescribe these various types of therapy in as specific a manner as he would medication. We feel that it is important to indicate where the work should be carried out, the length of the daily work period, the nature of the project, and the therapeutic aim in carrying out a particular type of work.

We regard occupational therapy, and to a lesser or greater degree every type of therapy as an excellent opportunity to meet a variety of emotional needs as a method of permitting aggressions in acceptable forms as a method of unconscious identification, as a method of propitiating unconscious guilt, as an outlet for the desire to create, and as a method of obtaining love. In our business man patient, occupational therapy did prove to be an opportunity for expressing aggressions which called for no punishment. He was first assigned the job of demolishing a part of a building, and his conscientiousness and enthusiasm were very evident. His feeling of well being gradually increased following the digging of a 2-foot foundation trench, and when

assigned to construction work he was convinced of the fallacy of his belief in his heart disorder, after he had sawed nearly a cord of fire wood.

The orders for medication for our patient included only barbitol for sleeping. However, this was disguised in hot milk, and the nurse was instructed to make no comments when giving it to him. This was desirable because he had taken a great many forms of sedative and, as with many neurotic patients, knew the shape, color, consistency and taste of most of the common sedative drugs. In this instance he immediately slept far better than he had for some time, even though, according to the history, he had previously taken larger doses of the same drug repeatedly.

In the orders for his diet the patient was instructed to go to the dining room, primarily for the socialization effect, and to be given a regular diet. Because he was underweight he was given between-meal nourishment. It will be noted that the order sheet permits even the detail of omitting silverware if that is advisable.

Through these orders we attempt to transmit to our nurses and therapists our conception of the patient's management. Preliminary orders are sent to the hospital within the first twelve hours of the patient's residence. Often our information is incomplete at this time, and we may not know any of the idiosyncrasies and peculiarities of the patient. Never is it possible on admission to forecast the unconscious identifications he may make for the people around him and hence his reactions to them. The admission orders do not necessarily afford a working plan beyond the first few days, and never beyond any marked change in the patient's condition. Consequently, following the presentation of the case at a staff meeting (usually within ten days after admission) a new set of order-sheets is written, and again at intervals of not more than thirty days.

The training of the nurses and therapists in psychiatry and the giving to them of an outline of the program of therapy are all only preliminary to the treatment of an individual case. We have also worked out a reasonably successful plan for supervising the execution of these orders. Its description, however, would be of interest chiefly to hospital administrators.

In a description of this plan it has been my intention to present the positive observations and experiences that have evolved from a trial of some years. To this point I have purposely neglected to introduce the many unsolved problems involved, some of which may be briefly indicated. Our plan is inadequate to meet the problems of the chronically ill patient who shows marked regression. We are perplexed in the therapeutic management of the masochistic individual who cooperates too well in all aspects of the program and doggedly fulfils every prescribed activity. A major problem is present in securing the cooperation of a variety of patients who assume the attitude that our plan isn't the right one for them. I have not mentioned the problems presented by the relatives of patients, who often obstruct our program intentionally or unintentionally.

We are carrying on some research in other problems concerned with this plan. As mentioned, we attempt to indicate our therapeutic aims in each case, but the method of achieving this aim is difficult to determine in specific types of therapy. At present we are attempting to classify our occupational activities into groups which most effectively meet these various therapeutic aims. We hope to determine from observation and controlled experimentation, for instance, the most effective

tive type of work and use of tools to permit the expression of hostility, to propitiate a feeling of guilt, and the like. For some years we have been experimenting with certain reading material as a therapeutic agent, specifically the desirability of mental health literature both fiction and nonfiction and the desirability of historical and travel books over fiction.

The inference is that from these research problems we expect to learn much more about the specificity of treatment for the mentally sick individual and how and why various therapeutic measures are successful or unsuccessful.

3617 West Sixth Street

CONTRIBUTORY CAUSES OF CORONARY THROMBOSIS

CADIS PHIPPS, MD

BOSTON

If the prophylaxis of coronary thrombosis is possible in a practical way, it must be based not only on an understanding of basic conditions, such as atherosclerosis but also on a recognition of, first, the individual liable to an attack and, secondly, exciting or precipitating factors. In considering susceptibility, the presence of peripheral arteriosclerosis forms merely a general background and even the now possible x-ray visualization of advanced coronary changes is of but little practical help when it is realized that even then the vessel may be patent or, for that matter, that total obliteration, if gradual, may be symptomless.¹ Characteristic electrocardiographic changes occur after the occlusion, and the term "arteriosclerotic heart disease" is too inclusive and inaccurate. That there are anticipatory symptoms and signs is suggested by the following statistics of cases treated at the Boston City Hospital and supplemented by records from my personal practice. Obviously, many records of proved coronary disease have to be discarded because of inadequate histories obtained.

Table 1 needs a few words of explanation and comment. The first group of 15 per cent gave no past history of real significance. Obviously, the largest group comprises those patients who have suffered from a previous attack of coronary thrombosis or have been subject to angina. By "dyspnea" I mean excessive difficulty in breathing on even slight exertion, but without pain and without discoverable underlying cause such as allergy or a pathologic condition of the lungs. Although paroxysmal nocturnal dyspnea was present in only 7 per cent of the cases, I feel that it is a most important symptom. I am using the term "myocardosis" rather than "stenocardia" or "arteriosclerotic heart disease," for I believe that a more concrete symptom complex exists if it is restricted to cases presenting that triad of symptoms: palpitation, dyspnea and precordial discomfort or pain described by Biering² and others with perhaps minor clinical and electrocardiographic changes. The abbreviation "sweating" refers to the very small group (2 per cent) in which there was a history of acute exhaustion and profuse sweating on slight exertion.

I have felt hesitant in recording the last group labeled "indigestion." The reaction to the term may

be either that digestive difficulties are too common to be significant here or else that this so-called indigestion is a mistaken interpretation of coronary symptoms (which it may well be). However the term is restricted to those patients who, only a few months prior to their coronary attack, have complained (and for the first time) of abdominal distention, gas and some nausea, these symptoms being related to meals and especially to hurried or excessive eating and relieved markedly by belching or vomiting. Add to this a complete absence of discoverable gastro-intestinal disorder and also an unexplained and rapid increase in the frequency and severity of the attacks, as a rule, until they have merged into a real coronary disaster.

The converse of this table is perhaps of more interest. Coronary thrombosis develops in more than half of all cases of angina pectoris. Myocardosis is definitely a degenerative heart disease and dependent on coronary disease. Dyspnea, otherwise unexplained, and marked on slight exertion in a middle-aged individual is more than suggestive of underlying coronary disease. Statistics relative to underlying hypertension I have omitted, as they are confusing and, when based on the patient's history, inaccurate. Its incidence has been placed variously at from 20 to 40 per cent. Conversely, the incidence of coronary deaths in hypertension probably lies between 6 and 10 per cent.³ While premonitory physical and laboratory signs, singly, are not characteristic, they may, in combination or in association with symptoms, be diagnostic. The clinical observations in myocardosis, with perhaps some variation of the contour of the ST wave or lengthening of the auriculo-ventricular, QS or QT interval, may be enough to make a presumptive diagnosis. For that matter, bundle branch and marked auriculoventricular block, together, are practically pathognomonic of coronary thrombosis, and the prominence of Q₃, I believe, merits further study in this connection with especial emphasis on its recognition by Hurvath's⁴ methods.

With regard to table 2, let me point out that in about 60 per cent of the cases the attack was in no way related to physical stress. Of the remaining 40 per cent exer-

tion was, in 17 per cent of the total, only moderate, such as walking or running a machine, and also that more than one half of these attacks (forty-three out of seventy-seven cases) during so-called exertion occurred within an hour after the ingestion of food. Drew Luten⁵ made the following observation: "Evidence suggests that coronary constriction induced by gastro-intestinal reflexes may also occasionally play a part in thrombosis." The first group, labeled "exercise," includes not only violent exercise, such as running but also such exercise as golf, and I have also included the possible stress of surgery and general infections under

this title. In the larger group occurring while the patient was at rest (either lying, sitting or at most walking about in a house) 12 per cent occurred after eating and 5 per cent of the patients had been on large doses of digitalis. The relationship to the administration of epinephrine and insulin needs no comment. Dehydration, with possible resulting increase in blood viscosity,

TABLE 2—Precipitating Causes in 437 Cases

	Cases	Approximate Percentage	
Physical stress			
Exercise	57	13	98 cases (23%)
Surgery	26	6	
General infection	15	3	
Moderate or usual exertion (43 cases after eating)			
After eating	4	12	77 cases (18%)

Larval	11	2	
Sleeping			
No cause			36 cases (8%)

although present in but a small group, was the only discoverable exciting cause in twenty-seven cases (as was also the case in the group occurring after the ingestion of food). Malnutrition might perhaps be added to this, because of both clinical and theoretical similarity. "No cause" is self explanatory, and by "larval" I mean that type of coronary thrombosis in which the onset is indefinite because so gradual. The group entitled "sleeping" I have again specified as having "no cause," for I believe that the theory that an attack occurring during sleep is precipitated by troubled dreams is untenable, for, both logically and also from an analysis of case histories, its converse would seem true, namely, that the thrombosis has caused the nightmare (even as indigestion may).

From these figures it would seem that it should be possible to foretell attacks of coronary thrombosis in the majority of instances. There is not only the obvious group of patients suffering from angina pectoris or having had a previous occlusion of the coronary artery, comprising about 40 per cent of the total number of cases, but also other signs and symptoms, such as paroxysmal nocturnal dyspnea, which are almost pathognomonic, especially if in combination, and I believe that my estimate of only 17 per cent of the cases giving no history of suggestive signs or symptoms is modest. It is the precipitating causes, however, which I wish to stress, although I realize that there are probably many omissions, such as thyroid dyscrasia or sensitivity to tobacco, which perhaps should be considered. The possible untoward effect of digitalis needs no comment. My observations are, in a way, merely statistical corroboration of work previously done by Gilbert and Fenn⁶ and others. Recently there was an excellent discussion by Master⁷ on the value of a low calory diet in coronary thrombosis. I have approached this in a different manner, namely, by frequent small feedings (even during the night and early morning hours), in patients suffering from anginal attacks. Furthermore, the influence of dehydration and even malnutrition is perhaps explained by the work of Roemheld and Babkin, as quoted in this article by Master

To my mind, the most important consideration is the infrequency of physical stress (occurring in only 40 per cent of the cases) as a precipitating cause and, conversely, the greater number of attacks occurring during rest. Luten,⁸ in commenting on the occurrence of coronary thrombosis during sleep, drew attention to the impoverished coronary circulation due to lowered diastolic pressure and decreased systolic output, most marked during the early morning hours. It might be interesting to speculate on the work of Zwaardemaker⁹ and Schwartzman¹⁰ and their claims to have isolated a substance not only from the myocardium but also produced by activity in skeletal muscles, which increases coronary flow. However, it is simpler to base one's conclusions on clinical observation, for it is known that the ordinary patient suffering from angina pectoris, even if it be angina of exertion, is benefited by carefully graded exercise. A recent study,¹¹ which was based on 500 cases of heart disease in workmen whom I examined impartially for the Massachusetts Industrial Accident Board, persuaded me that the manual laborer who has heart disease but who, for economic reasons must continue working, has a better life expectancy and also a much later advent of cardiac incapacity than the so-called private patient or "white collar" worker. A consideration of the anatomy and physiology of the coronary arteries, in addition to careful analysis of case histories, leaves a great doubt in my mind concerning any definite causal relationship between physical stress and coronary thrombosis.

THE BLOOD CYANATES IN THE TREATMENT OF HYPERTENSION

M. HERBERT BARKER, M.D.
CHICAGO

A few years ago I gave a number of patients with hypertension potassium or sodium thiocyanate with results that were generally unsatisfactory. Some showed extreme weakness, nausea and dizziness, while an occasional one seemed to be considerably improved as far as the symptoms and blood pressure level were concerned. In general, it seemed that older patients or those who had a blood pressure elevation over a long period of time seemed to tolerate cyanate therapy less well than the younger group. Careful observation indicated that individual dosage was necessarily dependent on the individual response and the toxicity. An attempt has been made, therefore, to gage the dosage by a study of the cyanate clearance from the body through the urine and a correlation by the blood cyanate level and the blood pressure. The following material is being presented as a preliminary report on such observations extending over a period of four years.

LITERATURE

The pharmacology of the cyanates is very little understood. Claude Bernard¹ made the first observations, which were reported in 1857, and he regarded them as a muscle poison which abolished muscular

activity Paul² and LeRoy³ independently noted decreases in blood pressure while studying the cyanates. Nichols⁴ reviewed the pharmacologic and therapeutic properties of thiocyanates in 1925. Schreiber⁵ showed that it took from two to three weeks for cyanates to return to normal levels in the saliva and in the blood after the administration was discontinued. He indicated that toxic manifestations in the normal individual appeared when the blood cyanates reached 40 or 50 mg. More recently Healy⁶ has shown that the cut surface of the adrenal body was strongly positive for the thiocyanates in the cortical portion when potassium thiocyanate was administered to rabbits, which suggested the possibility of the accumulation of the drug in the adrenal. Smith and Rudolf⁷ administered sodium thiocyanate to normal individuals. The cyanate was stopped when the blood pressure fell below 100, and none complained of symptoms. From one to eight weeks' time was required for the blood pressure to return to the previous normal level.

A review of the clinical literature brings a great divergence of opinion on the value of the administration of cyanates in hypertension. Goldring and Chasis⁸ noted a constant relation between the persistence of the hypotensive effect and the amount of thiocyanate administered. They cautioned that the dose should not exceed 5 grams (0.3 Gm.) daily and that the drug should be discontinued at the first indication of nausea, fatigue or vomiting or with the first distinct fall in blood pressure. Contrary to opinions generally expressed, these authors feel that thiocyanate carefully administered is just as effective and no more apt to produce toxicity in the patient with glomerulonephritis than in hypertension. Their reports on fatal cases, however, show no antemortem blood studies for cyanates. Representative toxic manifestations have been reported by Palmer and Sprague⁹ and others.¹⁰ Some¹¹ are strenuously opposed to the administration of cyanates. Others¹² report no toxic effects in patients closely observed. A review of the individual protocols of dosages reported by the various authors indicates that patients given larger doses more regularly suffered

toxic manifestations, while those who gave small doses reported little or no toxicity and often no decrease in blood pressure.

MATERIAL AND METHOD

This report covers observations on forty-five patients with systolic blood pressures well over 200, who have been personally studied in the renal clinic and in private practice during a period of from one to four years. The technic consisted in selecting patients who had been seen regularly and whose blood pressures were followed through periods of from one to four years on various forms of therapy. This should familiarize one with individual variations, influence of seasonal changes and the like, or factors that are so important in evaluating any therapy in this group, as emphasized by Ayman,¹³ Davis¹⁴ and others. The patients have been repeatedly studied from the cardiorenal-vascular standpoint, but the details of this work are too extensive to be included here.

It was thought that the factor of individual variations in toxicity might be avoided or controlled by following the blood cyanate level. If so, it was thought that a dose of cyanate might be attained which would reduce blood pressure without causing toxic symptoms.

A modification of Schreiber's⁵ technic for the determination of thiocyanates in the blood was developed, which has been simple, once the following standards were made up.

THE ESTIMATION OF THIOCYANATES IN THE BLOOD

Solutions—1. Ten per cent trichloroacetic acid solution.

2. Ferric nitrate reagent. Dissolve 50 Gm. of crystallized ferric nitrate in 500 cc. of distilled water. Add 25 cc. of concentrated nitric acid and make up to 1 liter with distilled water.

3. Thiocyanate standards. Stock solution. Dissolve about 1 Gm. of potassium thiocyanate in 800 cc. of distilled water. Titrate a 20 cc. portion of a standard silver nitrate solution (made by dissolving exactly 29.195 Gm. of silver nitrate in 1 liter of distilled water) acidified with 5 cc. of concentrated nitric acid, with the potassium thiocyanate solution, using ferric ammonium sulfate as an indicator. Calculate the amount of water which it will be necessary to add to the potassium thiocyanate solution to make 20 cc. equivalent to 20 cc. of silver nitrate solution. Add the calculated amount of water, mix thoroughly and check the solution by another titration to make sure the potassium thiocyanate solution is exactly equivalent to the silver nitrate solution.

Standard solutions. Make three dilutions of the stock solution to give the following three standards: (1) 100 cc. of stock diluted to 1 liter with water gives a standard which contains 0.5 mg. of the thiocyanate ion in 5 cc. of solution. (2) 70 cc. of stock diluted to 1 liter with water gives a standard which contains 0.35 mg. of the thiocyanate ion in 5 cc. of solution. (3) 40 cc. of stock diluted in 1 liter with water gives a standard which contains 0.2 mg. of the thiocyanate ion in 5 cc. of solution.

Method.—Transfer 5 cc. of the 10 per cent trichloroacetic acid solution to a test tube. Add 5 cc. of serum or plasma. Stopper and shake well. Allow to stand from ten to fifteen minutes. Filter through a small filter paper. The filtrate should be perfectly clear. If it is not filter again through the same filter paper. Measure 5 cc. of the filtrate into a clean, dry test tube. Add 1 cc. of the ferric nitrate reagent. Mix and read in a colorimeter with the standard solution set at 20 mm., choosing that standard which most nearly matches the unknown. The standards are made as follows: Transfer 5 cc. of each of the three standard solutions to three test tubes. Add 5 cc. of trichloroacetic acid solution and 2 cc. of the ferric nitrate reagent to each. Mix.

Calculation—With the standard solution set at 20 mm for the colorimetric comparison the calculation may be simplified to the three following forms, depending on the strength of the standard

- 1 Using the 0.5 mg standard, 200/reading-mg of the thiocyanate ion in 100 cc of serum
- 2 Using the 0.35 mg standard, 140/reading-mg of the thiocyanate ion in 100 cc of serum
- 3 Using the 0.2 mg standard, 80/reading-mg of the thiocyanate ion in 100 cc of serum

Before the patient was started on cyanate, all therapy was discontinued and control observations for cyanates in the blood and urine were made. The patients were then given 0.3 Gm of potassium or sodium thiocyanate daily. They were seen twice a week for the first two weeks and once a week thereafter until an equilibrium between the dosage of cyanate and blood pressure was established. Blood cyanate determinations were made at each visit. A number of patients were hospitalized and then given doses of from 0.3 to 1 Gm daily for a number of days, until sharp falls in blood pressure or toxicity were noted. Daily cyanate determinations were made on the blood and urine of this group. The urine clearance of cyanates varied greatly, and that feature will be discussed at a later date as a factor of individual tolerance. In the main, no clear-cut information has been gained from the urine clearance alone, but there was a fairly good correlation between the blood cyanates, the toxicity and the reduction of the blood pressure.

RESULTS AND COMMENT

Whenever the cyanates in the blood were raised above 5 or 10 mg, a fall in the systolic and diastolic blood pressures occurred in thirty-five of the forty-five patients studied. Slight toxic manifestations, namely, weakness, ease of fatigue and dizziness, were noted in many of these patients but were not especially disturbing until the blood cyanates were raised above 10

Chart 1—Clinical course in case 1

or 15 mg. Toxicity increased rapidly above the blood level of 20 mg, but serious manifestations were not noted until levels from 35 to 50 mg were reached. From the standpoint of the relief of symptoms and the drop in blood pressure, it seemed that a blood cyanate level from 6 to 10 mg was ordinarily required. The dosage was found to be individual in each case. For example, one patient required a dosage of only 60 mg, while another required 720 mg a day to maintain a

blood cyanate level of 10 mg. As the cyanate clearance through the kidney improved, the dosage had to be gradually increased during the weeks that followed, if the blood pressure and the blood cyanate levels were to be maintained.

It will be impossible to go into the many details incident to the observations and care of this group of

Chart 2—Clinical course in case 2

patients, but charts 1 and 2 will indicate typical experiences in general.

Early in the study of two of these patients, severe weakness, vascular collapse and cerebral thrombosis with ultimate recovery was experienced. Both patients had had severe hypertension of long standing and their pressures ranged from 250 to 275 most of the time. The neurologic evidence of thrombosis occurred twelve and thirty-six hours after the vascular accidents were noted. In both of these patients the blood cyanates were found to have risen sharply to levels of 33 and 45 mg respectively on doses considerably under that recommended in the literature. Without the blood cyanate observations, no doubt such responses would have been regarded as merely intolerance to the drug rather than to an actual overdosage. Such experiences also cause me to suspect that deaths may have occurred in the past, in the course of cyanate therapy, which may have been attributed to the vascular accidents common to the patient with vascular disease (charts 3 and 4). Two other patients were carried to 35 mg per hundred cubic centimeters without collapse. One complained of much fatigue with only slight reduction of the blood pressure, while the other one complained of great fatigue and somnolence associated with a sharp fall in the blood pressure (chart 5). The return of the blood pressure to the previous high levels lagged behind the reduction of the blood cyanates. This experiment was repeated several times, and the blood pressure was now maintained at from 150 to 180 mm by a dosage of potassium thiocyanate, which maintains a blood cyanate of 10 mg.

Of the forty-five patients studied with the blood cyanate level controlled, no two have been found that were comparable. Thirty-five of the forty-five have responded with respect to symptoms and blood pressure levels in essentially the following way. A dosage of 0.3 Gm a day usually was associated with a decrease in nervousness, diminution of headaches and often a beginning fall of blood pressure in from five to seven

days. At this time the blood cyanates were generally found to be between 5 and 7 mg per hundred cubic centimeters. The patients then frequently complained of fatigue. Insomnia often changed to somnolence and the blood pressure generally fell from 30 to 50 mm in the first ten or fifteen days. At that time the blood cyanates were commonly found to be between 8 and 10 mg per hundred cubic centimeters. To prevent elevations over 10 mg the dosage was now decreased to 0.3 Gm three or four times a week. If the blood cyanates were then found to be 10 mg or over, the administration was discontinued, because, in the instances in which the blood cyanate level rose above 15 mg increasing symptoms of toxicity were noted. A peculiar aching of the legs and body disturbed an occasional long standing case. Quite a number of patients commented on their increased urinary output. Some of this group had congestive heart failure so that such a diuresis was associated with a return of compensation and loss of edema. A reduction in the size of the heart of four patients was noted. Such responses indicate the importance of the reduction of the load on the cardiac mechanism. One young patient with severe hypertension now under control has noted a great increase in seminal fluid formation which has persisted for several months. In some patients treated over a long period a severe anemia has developed.

As reported by Borg,¹⁰ this study has not revealed any difference between the sodium and the potassium salt. The toxic manifestations, hypotensive effect and blood levels for these two salts have been essentially the same. No skin manifestations have been noted to date. Three patients have shown a peculiar myxedematous swelling of the tissues of the face, orbital areas and cervical regions. One occurred in a woman after one year and the other occurred in a woman after fifteen months of the administration of cyanate. In the latter

troubling relation to the cyanate therapy, but they cause one to be alert for other evidences of possible endocrine effect. One cannot help recalling the diffuse thyroid enlargement noted in rabbits after the feeding of cabbage, which has been considered to be possibly of cyanate origin.

Ten of the forty-five patients showed little or no response to cyanate therapy. Two of this group

Chart 4—Clinical course in case 4

required larger doses (0.6-1 Gm daily) to maintain the blood cyanates over 8 mg. No relief of blood pressure or its attendant symptoms could be otherwise obtained. Symptoms of toxicity, especially fatigue, often were as annoying as those of the hypertension. Although occasionally one of these patients felt better on such doses, it has been difficult to keep the pressure below 200 mm. Attempts to effect a further reduction were attended by toxic manifestations, and the cessation of cyanate therapy was soon followed by a return of the blood pressure to its former levels of from 230 to 280, with all the old symptoms. Three of this group showed no immediate response, but, on a dosage sufficient to maintain a blood cyanate level of from 9 to 15 mg for from three to four months, a cessation of the fluctuations to high levels was noted. In these patients the systolic pressure appeared to stabilize at the lower level, namely, about 200 mm for a time and then a gradual reduction of both systolic and diastolic levels occurred, so that these three patients are now maintained around 150 or 170 mm. The remaining five patients showed no response other than toxic manifestations of a severe degree. Although the reason for the patients to fail to respond to cyanate therapy is not clear, it was evident that the most resistant cases presented well advanced arteriosclerosis. Some older patients with severe hypertension of several years' standing were 'cyanate sensitive' and have been almost as easily stabilized as any of the younger nonsclerotic group.

In general, if the patient is found to be able to tolerate the cyanates it seems much more satisfactory to effect a gradual reduction of the blood pressure so that he may become adjusted to the change. After the blood pressure has been maintained at a lower level for from one to three months a great improvement of the patients' symptoms is generally noted. The first period of weakness passes and a feeling of well being and a return of energy follow. Although the complications are many and varied the benefits derived in those

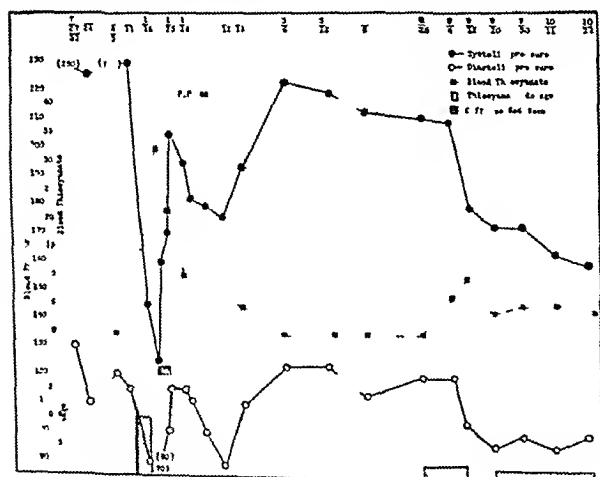

Chart 3—Clinical course in case 3

a large thyroid hoarseness, swollen face and heavy jaws developed. The basal metabolic rates were only slightly reduced (-18 — -9). In one man a diffusely enlarged thyroid gland developed after ten months' administration of potassium thiocyanates. His basal metabolism had fallen from $+19$ to -9 . The enlarged thyroids returned to normal size on the administration of desiccated thyroid. Such observations have ques-

¹⁰ Borg, J. I. Experiences in the Use of Sulphocyanates. *Minneota Med.* 13: 303 (May) 1930.

responding favorably, as manifested by a decrease in blood pressure with the relief of subjective symptoms and congestive heart failure together with the improvement of urea and uric acid clearance, the reduction of total serum proteins and phenols in the blood so frequently noted would indicate that the cyanates are worthy of further study

SUMMARY

Forty-five patients with hypertension have been given sodium or potassium thiocyanate and the concentration of the cyanates in their blood has been followed. The reduction of blood pressure and the relief of symptoms obtained in thirty-five of the forty-five roughly corresponded to the level of the cyanates in the blood. The optimum therapeutic level would seem to range between 8 and 12 mg per hundred cubic centimeters and significant toxicity begins to appear at from 15 to 30 mg. The individual tolerance varies greatly, the different levels being obtained with widely varying doses. The cyanates may reach hazardous concentrations very quickly in some individuals, so that the administration of the thiocyanates is believed to be dangerous unless controlled by close observation and blood cyanate determinations.

REPORT OF CASES

CASE 1—A H M, a man, aged 56, an executive under observation for three years, complained of nervousness, heart consciousness tremor and occipital headaches. Blood pressure

Chart 5—Clinical course in case 5

fluctuations were noted between 190 and 230 systolic and 120 and 130 diastolic the average being 200/120. A dosage of 1 Gm of potassium thiocyanate for four days was followed by a drop in both systolic and diastolic pressure. A fluctuation of readings was noted for a few days, followed by a leveling of the pressure at about 165/110 on 0.6 Gm (chart 1). During the past two years his blood pressure has been maintained between 155 and 170 systolic and 90 and 100 diastolic on a dosage which maintains the blood cyanates at about 10 mg. A complete relief of symptoms was noted after the first three months of cyanate therapy. His maintenance dose is between 2 and 3 Gm a week. Two attempts at stopping the drug were associated with a return of blood pressure elevation and symptoms after about four weeks.

CASE 2—B K, a housewife, aged 40, complained of severe pounding occipitofrontal headaches, dizziness, ringing in the ears, nervousness, insomnia, emotional instability, heart consciousness and weight loss. A known hypertension for five years and personal observation for one year revealed a blood pressure of 195-230 systolic and 100-130 diastolic the average being 215/120. A dosage of 1 Gm of potassium thiocyanate for two days was reduced to 0.3 Gm, and in sixteen days the fluctuant period had passed and the patient's blood pressure was rather constant at 165 systolic and 110 diastolic (chart 2). She was most grateful because she was now sleeping very well and was entirely free from headaches. The blood cyanates

increased to 15 mg by the nineteenth day after the cyanate therapy was started and she started to complain of fatigue and somnolence. The cyanates were discontinued for one week and a return of pressure began, which was again reduced with readministration of the drug. The maintenance dose was found to be 0.2 Gm of potassium thiocyanate for the next two months and during the next eight months was 0.3 Gm daily. The blood cyanate level noted at the optimum blood pressure readings was between 8 and 10 mg.

CASE 3—F P, a man, aged 68, a retired broker, admitted to the hospital Aug 27, 1933, had had a severe hypertension for a known duration of five years, with moderately severe congestive failure. A diuretic regimen of low sodium diet, ammonium nitrate, digitalis and mercurials brought him to a fair circulatory balance, but as soon as he was allowed up or out of the hospital the congestive failure returned. The blood pressure ranged between 238 and 250 systolic after six months of care. He was markedly sclerotic but it was decided to try cyanate therapy. He was given 0.6 Gm of potassium thiocyanate and on the fourth day he became pale, very weak and confused, and the blood pressure fell to 124/70 within a few hours. A cerebral thrombosis with a right hemiplegia, loss of speech and difficulty in swallowing came twelve hours later. The blood cyanates were found to be 33 mg. Caffeine with sodium benzoate in 5 grain (0.3 Gm) doses every two hours seemed to revive the vascular tone (chart 3, 1/16/34). The cerebral lesion gradually cleared and the blood cyanates returned to normal in fifty days. The blood pressure returned gradually to somewhat over 200 and the heart failure reappeared. A cautious resumption of a dosage of 0.2 Gm of potassium thiocyanate again caused a sharp fall of the blood pressure and later the maintenance dose was found to be 0.1 Gm. Renal clearance has improved so that one year later he requires 0.5 Gm potassium thiocyanate daily to maintain a blood cyanate of 8 to 10 mg. He seems to be in splendid health without diet, rest or any other form of therapy. The blood pressure averages 160/100.

CASE 4—R C, an executive, aged 52, who had had a severe hypertension of seven years' duration, had had a cerebral hemorrhage with slight residuals five years before this study was made. Personal observation of two years had shown blood pressure fluctuations of 240-300 systolic and 140-170 diastolic, and a moderately severe congestive heart failure was present much of the time despite energetic therapy. Sedatives and venesections reduced the average pressure to 210/130 on three periods of hospitalization. Within two or three weeks after the patient resumed activity the blood pressure would be found at the previous high levels. He was again hospitalized and after his blood pressure seemed stabilized ten doses of 1 Gm of potassium thiocyanate administered on consecutive days were associated with a significant drop of the pressure (185/110). The medication was stopped and the blood pressure soon began to return to its former level. After discharge from the hospital he was instructed to take 0.6 Gm of potassium thiocyanate daily and to return biweekly for observation. The patient drank the medication directly from the bottle without measuring the dosage and he was found at home in vascular collapse (chart 4, 1/16/34) with a blood pressure of 128/80. Large doses of caffeine with sodium benzoate seemed to revive him greatly and the blood pressure rose much after the manner noted following caffeine administration in quinidine intoxication. His blood cyanates were found to be 45 mg and it required nearly four months for them to return to normal. During the first half of this recovery period the patient was disoriented, confused and extremely weak. There was a marked defect of speech. The return of the blood pressure with resistant heart failure caused a cautious resumption of the thiocyanates. At first 0.3 Gm a week was sufficient to maintain a 10 mg blood cyanate level and an associated blood pressure of 180-200 systolic and 90-110 diastolic. The renal cyanate clearance has improved in the past year so that it is necessary to give 3 Gm a week to maintain the blood cyanate level of 10 mg. During this period the heart failure has not returned and the pressure remains slightly under 200/110, which he seems able to sustain without untoward effects.

CASE 5—A S, a woman aged 52 unemployed had had a known hypertension of sixteen years duration. She had been

under my personal observation for two years prior to this study. Her symptoms were headache, insomnia, emotional instability, nocturia and chronic congestive heart failure. Her record is striking in that she was "cyanate sensitive," and the blood cyanate and the blood pressure curves are quite reciprocal. At first a dosage of 0.3 Gm would raise the blood cyanates to 35 mg and the blood pressure would drop sharply. This fall continued for about three weeks after the drug had been discontinued (chart 5). Extreme fatigue was associated with elevations of blood cyanate over 15 mg. Renal clearance of cyanates gradually improved so that as time went on the dosage period required to raise the blood cyanates to the previous level of 35 mg had to be increased. Chart 5 shows this relation clearly, and it also shows that the patient had now reached a continuous dosage of 0.3 Gm of potassium thiocyanate daily in order to maintain a blood cyanate of 10 mg. This level of blood cyanates has continued to be associated with a blood pressure of 170 systolic and 110 diastolic most of the time. It is noteworthy that the patient has been without any dietary program or cardiac therapy for one year and feels quite well. She sleeps well and suffers no more headaches, and the emotional state is normal.

THE TRAINING OF INTERNS IN SYPHILOLOGY

IN HOSPITALS APPROVED FOR INTERNSHIPS

WALTER CLARKE, MD

AND

MAX J. EXNER, MD

NEW YORK

It is conservatively estimated, on the basis of reliable data from many sources, that the prevalence of syphilis in the United States is about 5 per cent of the population, or approximately 6,000,000 men, women and children. Extensive authoritative studies have shown that at any one time not more than one tenth or one eleventh of the total existing cases of syphilis are under medical care. The vast number of unrecognized cases still constitutes one of the major public health problems.

The role of the private physician in the control of syphilis is necessarily an important one, since many of the unrecognized cases pass through his hands and will go untreated if he does not discover them. It has been shown that as yet about 72 per cent of all known cases of syphilis are under treatment by public clinics and specialists. The inadequate role that the private physician plays in the matter is one of the great obstacles to the control of syphilis.

Two questions are therefore pertinent: (a) How generally and effectively do the medical schools prepare their students for the modern diagnosis and treatment of syphilis? (b) To what extent do hospitals provide practical training and experience in the matter in the training of interns?

In 1933 the American Social Hygiene Association made a study of instruction regarding syphilis in American medical schools.¹ It showed a very wide range of standards from the worst to the best in this regard. In less than half the schools the standards of teaching about syphilis seemed reasonably satisfactory, and in only a few schools high. In many of the rest the standard was extremely low. The conclusion was reached that it was urgent that the standard which prevails in the best schools in this matter become more nearly the common standard of all the schools.

A study has now been made of the practices of hospitals, approved for internships, in training interns in syphilology, by the Council on Medical Education and Hospitals of the American Medical Association in cooperation with the American Social Hygiene Association.

Five hundred and ninety-four hospitals in forty-two states answered the inquiry. The number of hospitals by states range from one in each of four states to

TABLE 1—States Sending Largest Number of Replies

New York	84	Massachusetts	33
Pennsylvania	67	Ohio	32
Illinois	43	California	30
New Jersey	34	Michigan	24
Total			347

eighty-four in one state, namely, New York. States in which the largest number of replies were received are given in table 1.

Of the 594 hospitals reporting, 331 have an outpatient service and 263 have not.

Wide variation among states is shown in the proportion of hospitals having an outpatient service. For example, for the states leading in numbers of hospitals (table 1) the proportions are as given in table 2.

Of the total 331 hospitals that have an outpatient service, 314 make the syphilis service available to interns and seventeen do not.

Of the 314 hospitals that make the syphilis service available, 243 require the service of interns (twenty-one of these require it of some interns only) and seventy make the service optional. One hospital did not answer the question.

In this matter also of making the syphilis service a requirement of internships, there is a large range of variation among the states (table 3).

Of the 314 hospitals in which syphilis service is available to interns, 304 report that in this service interns work under experienced supervision. The other ten did not answer the question. Experienced supervision is necessary if interns are to profit by service in an outpatient syphilis clinic, without such supervision the tour of duty in the syphilis clinic has little educational value for the interns but important risks for the patients.

DURATION OF REQUIRED SERVICE IN WEEKS

Of the 243 institutions that require syphilis service of interns, 228 indicate the duration of assignments in

TABLE 2—Hospitals Providing Outpatient Service

	Number of Hospitals	Outpatient Service Provided	
		Yes	No

Total	347	214	133

weeks. The assignments range from two weeks to thirty-four weeks, the average being ten weeks. The variation in leading states in the number of hospitals is shown in table 4.

A more true quantitative test of syphilis service requirements than assignments in weeks is the number

of hours devoted to it. In regard to this an even greater variance is found to exist. The highest requirement is 720 hours, the lowest is six hours, and the average is fifty-eight hours.

The average standard of requirement in these 243 hospitals is, then, an assignment of ten weeks to syphilis service at a little less than six hours per week, or a total of about sixty hours.

The record of assignments in hours in the leading states is given in table 5.

Minnesota	7	8	2	6
Total	184			

It may be noted that the four states which lead in high and in average assignments in weeks are, in order, Wisconsin, New York, Texas and Ohio, whereas the four states which lead in assignments in hours are, in order, Massachusetts, Ohio, Minnesota and New York (table 6).

When all the states are considered, regardless of the number of institutions, the highest average records in hours assigned to syphilis service are held by Iowa, Virginia, Alabama and the District of Columbia (table 7).

DURATION OF OPTIONAL SYPHILIS SERVICE IN HOURS

Of the seventy institutions in which syphilis service by interns is made optional, only fifty-nine state the percentage of interns who avail themselves of the opportunity and forty-seven give the number of hours devoted to it as is shown in table 8.

COMMENT ON DATA

With regard to syphilis service being made available to interns it may be suggested that the noteworthy fact is not that of 331 hospitals which have an out-

patient service 314 make the syphilis service available, but rather that as yet seventeen hospitals do not make it available.

One of the most striking and significant facts of this study is the wide variation among the hospitals in the assignment of interns' time to syphilis service, ranging from a low of two or three weeks in five hospitals to a high of thirty-four weeks in one hospital, and a low of six hours to a high of 720 hours. While other factors undoubtedly enter in, the wide diversity in the policies and practices of hospitals in this matter may in the main be taken to measure the degrees of conviction on the part of hospital authorities as to the importance of training interns in the modern diagnosis and treatment of syphilis. The importance of syphilis as a public health problem and the fundamental role played by the private general physician in attempts to solve this problem would seem to leave no question as to the importance of a uniform policy on the part of all hospitals training interns of aiming to prepare all medical graduates to diagnose and treat at least the ordinary, uncomplicated cases of syphilis.

		High	Average
Iowa	2	208	168
Virginia	2	300	134
Alabama	3	200	170
District of Columbia	4	300	106

In view of the extremely low standards of requirement in some hospitals in this matter, it would seem reasonable to suggest that all hospitals now requiring less than the average period of syphilis service, namely ten weeks including sixty hours, should as soon as possible attain at least this as a minimum period of service in the syphilis clinic required of interns.

It was shown that, in hospitals in which syphilis service by interns is made optional, the percentage of interns who avail themselves of the opportunity ranges

from a low of none in one state to a high of 100 in eight states (In four of these eight states only one institution in each state is represented) The average percentage by states of interns who take syphilis training ranges from 33 to 100

We observe also that the number of hours devoted by interns to optional syphilis service ranges from a low of ten to a high of 300, the average range, by states being from ten to 109 hours In eight of the seventeen states that report the optional hours devoted to syphilis service, the average falls below fifty hours While much improvement in this matter is called for there does seem to be a fair degree of spontaneous interest in the subject of syphilis on the part of interns

CONCLUSIONS

Training of interns in syphilology constitutes a vital factor in the control of syphilis

In the seventeen hospitals that have an outpatient service but do not make the syphilis service available to

TABLE 8—Duration of Optional Syphilis Service

interns, a reconsideration of policy is to be recommended

In the seventy institutions that leave syphilis service by interns optional, a change to required service of adequate extent is important as a measure toward the control of syphilis

The comparatively high standard of requirement that prevails in a considerable proportion of hospitals needs to become more nearly the common standard of all hospitals It seems reasonable to expect that none should fall below the present average, namely, ten weeks, including sixty hours of required syphilis service under experienced supervision

50 West Fifth Street

Bones as Human Food—Bones are in fact, much more largely and widely utilized as human food than the people of western Europe and their descendants in the United States seem to realize. Nearly all other peoples are much more accustomed to eat the soft ends and porous interiors of the large bones of their prey or of such domestic animals as they may use for food while the bones of birds and small game are often munched entire, just as we eat bits of brittle toast. Studies of the food habits of the peoples of both the Near and Far East, of Eskimos, of American Indians, and of native African races have shown that all these peoples make large use of bones as foods—Sherman H C Food and Health New York Macmillan Company 1934

TOXICITY OF CARBARSONE

ACUTE FATTY DEGENERATION OF THE LIVER,
EXFOLIATIVE DERMATITIS AND DEATH
FOLLOWING ITS ADMINISTRATION

ERVIN EPSTEIN, M.D.

LOS ANGELES

P-carbamminophenylarsonic acid ($H_2O_2AsC_6H_4NHCNH_2$) is a comparatively recent addition to the armamentarium of the modern medical practitioner Its use dates back to January 1932, when it was introduced by Reed, Anderson, David and Leake,¹ although experimental studies were started at least two years previously This compound is marketed by Eli Lilly & Co under the name of carbarsone and is supplied in capsules of 0.25 Gm (3¾ grains) each It contains 28.85 per cent arsenic and has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association²

Although this product is an arsenical closely related chemically to tryparsamide and acetarsone ("stovarsol"), it is surprisingly nontoxic To date, no serious reactions or deaths have been reported following the rectal or oral administration of this drug In general, the pentavalent arsenicals, including tryparsamide and carbarsone, are less toxic than the trivalent group as exemplified by arsphenamine, neoarsphenamine, silver arsphenamine, sulfarsphenamine, bismarsen and mapharsen

The possibility of carbarsone producing fatalities by overdosage has long been recognized Reed, Anderson, David and Leake¹ quote minimum lethal doses for various laboratory animals However, the following case history is the first death and autopsy in a human being following the administration of carbarsone that could be found in the available medical literature

REPORT OF CASE

The history obtained of this patient was somewhat unsatisfactory During her stay in the hospital, she was irrational and disoriented, so it was necessary to obtain the history from her husband and from the private physician who took care of her during the month preceding her entry to the hospital

Mrs. A. J., aged 55, white, had suffered from anorexia and diarrhea for several months before she was seen by the previous physician She was having from eight to ten liquid bowel movements a day and some of these were said to have been black There was no history of nausea, vomiting or abdominal pain She visited a number of doctors and was given several medicines but she did not experience any relief and so did not continue their use for more than a few days before visiting another doctor No one knew the names of any of these physicians or the nature of the medicines she had taken

One month before entry she was seen by the practitioner who prescribed the carbarsone He states that at that time she was in very poor physical condition Examination of the stool revealed that it contained *Giardia* in large numbers but was otherwise normal

Therapy consisted of carbarsone, camphorated tincture of opium and ventriculin She took a total of 5 Gm of carbarsone by mouth during a period of ten days Another 2.5 Gm was administered in enemas, which were not retained As she

weighed 60 Kg (150 pounds), this represents a total oral dose of 833 mg per kilogram of body weight

Two days before entry she first complained of a pruritic eruption and the carbarsone was immediately withdrawn. Despite this the patient became disoriented and was admitted to the Los Angeles General Hospital on July 12, 1935.

On entry the patient appeared acutely ill but did not appear to be having any pain. She was unable to give any history and answered "no" to most questions. The mucous membranes were pale and the skin was dry, shiny, smooth and erythematous. The entire body was covered by a scaling eruption, which was most marked on the extremities, especially the lower ones. The scales varied in size but tended to be about the size of a half-dollar (30 mm). Numerous excoriations were present. There was no clinical evidence of jaundice.

The hair was dry, gray and lusterless. The eyes, ears, nose and neck were normal. No mucous membrane lesions were noted, although the lips were dry and the throat was slightly reddened. She was edentulous. Shotty, bilateral cervical and inguinal lymph nodes could be felt. The breasts were normal on inspection and palpation. The lungs were clear. The heart was slightly enlarged to the left but was otherwise normal. The systolic blood pressure was 120 mm of mercury and the diastolic pressure was 70 mm of mercury. The radial pulses were normal. The peripheral vessels were sclerotic on palpation. The abdomen was distended, the umbilicus flattened and there was nonshifting dullness in the flanks. Neither the liver nor the spleen was palpable. Other than the crustaceous dermatitis, the extremities showed no abnormalities. In general, the deep reflexes were sluggish but equal and the superficial reflexes were normal.

Laboratory studies on entry revealed a marked anemia. The blood count showed a hemoglobin of 46 per cent (Sahl) and 2,640,000 red blood cells per cubic millimeter of blood. The color index was 0.88. Slight anisocytosis, poikilocytosis, hypochromasia and polychromasia were present. The count further showed 5,650 white blood cells per cubic millimeter of blood. A differential count revealed 67.5 per cent polymorphonuclear leukocytes, 13.5 per cent lymphocytes, 4 per cent eosinophils and 15 per cent monocytes. The morphology of the polymorphonuclear leukocytes and the number of platelets appeared to be normal on the blood smear. The Wassermann and Kahn reactions on the blood were negative.

The urine was dark brown and had a specific gravity of 1.018. Its reaction was acid to litmus paper. A trace of albumin was present, but tests for sugar and acetone were negative. Microscopically a few red blood cells, white blood cells and epithelial cells were seen. No casts were noted. One test failed to demonstrate the presence of arsenic in the urine.

A large stomach tube was passed and a small amount of food that had been consumed twelve hours previously was aspirated. A gastric analysis was done later and neither free nor total hydrochloric acid could be demonstrated even after the injection of histamine.

The stools were liquid, and examination failed to reveal the presence of blood, purulent material or parasites.

Owing to the fact that none of the patient's skin was normal, neither patch nor scratch tests were performed with carbarsone.

Therapy consisted of sedatives (phenobarbital sodium and amytal compound), analgesics (codeine), high caloric diet, fluids (by mouth, subcutaneously and intravenously including dextrose), antianemics (ferric ammonium citrate and reduced iron), intramuscular liver injections, sodium thiosulfate intravenously (a total of 5 Gm), dilute hydrochloric acid in water with her meals, calcium gluconate by mouth and agents to control the diarrhea (camphorated tincture of opium and bismuth subcarbonate).

Local remedies employed included a bismuth and zinc oxide cream containing 1 per cent phenol, theobroma oil at night, starch baths daily and a lotion consisting of solution of coal tar N.F. 6 cc, zinc oxide, 24 Gm, corn starch 24 Gm, glycerin 36 cc and sufficient water to make 120 cc. Mix and apply locally as required.

Under this treatment the patient progressed satisfactorily for more than a week. The diarrhea was decreasing, the dermatitis was clearing and her general mental and physical con-

dition was improving. July 21 she was given a transfusion of 500 cc of citrated blood. Temporarily this aided her even more. However, the following day she vomited for the first time, vomiting up her lunch and supper. The next morning at about 1:30 she suddenly became weak, cold and lethargic. The radial pulse became very rapid and was difficult to obtain on palpation. Caffeine and epinephrine therapy produced only temporary improvement. She did not speak and showed no signs of recognizing any one. She scratched herself constantly, but when her hands were held away from her body she scratched the bedclothes or whatever was at hand. The reflexes were normal at this time.

Previously there had been a daily elevation of temperature to 38°C (100.4°F) but her temperature dropped to normal on July 22 and remained so until her death. Edema of the hands and feet developed coincidentally with a decrease in the urinary output to from 150 to 200 cc daily. A urinalysis just prior to death was approximately identical with the one already mentioned except that there was a large amount of bile and a slightly increased urobilin content. The test for acetone also was positive.

The diarrhea was never completely controlled but at the time of death had decreased to four liquid movements a day. The flatulence increased and was not relieved by turpentine stipes, enemas or the insertion of a rectal tube.

July 25 the patient first developed a visible icterus of the skin, although the sclerae were clear. The liver became enlarged and deep palpation in the right upper quadrant of the abdomen would cause her to wince. Some rigidity was present in this location. Her neck also became very rigid and a lumbar puncture was performed. The initial pressure was 160 mm of water and the Queckenstedt test was normal. A light greenish yellow fluid was obtained, which contained 20 lymphocytes per cubic millimeter of spinal fluid. The test for globulin was negative and the sugar content was normal. The Wassermann reaction was negative and the benzoin curve was 0000000000000000. The following day the icterus index of the blood was reported as being 100, while the nonprotein nitrogen was 80 mg and the creatinine was 27 mg per hundred cubic centimeters of blood.

Despite stimulation, the patient quietly died at 12:45 a.m., July 27.

An autopsy was performed nine hours after death.

The brain weighed 1,125 Gm and appeared to be grossly normal except for a slight dullness of the arachnoid and some generalized edema. Sectioning the organ revealed a moderate amount of cerebral arteriosclerosis. Histologic examination of the frontal region showed some sclerotic change in the nerve cells and there was a marked oligodendrogliosis in the underlying white matter, with phagocytized pigment in the perivascular spaces. Some of the nerve cells had undergone fatty degeneration. A section taken through the white matter demonstrated an increase in oligodendroglia with acute swelling of these cells but no evidence of petechial hemorrhage could be found. Examination of the medulla showed only engorgement of the blood vessels. The optic nerves were normal on macroscopic and microscopic examination. Chemical analysis revealed that the brain contained 0.02 mg of arsenic per hundred grams of tissue.

On exploring the thoracic cavity a few small adhesions were found at the apex of the left lung. The pleurae and pleural cavities were otherwise normal. Both lungs were crepitant throughout and cut sections showed only slight hyperemia. The left lung weighed 325 Gm, while the right weighed 375 Gm. Slight hyperemia could also be noted on microscopic examination but no evidence of pneumonia was found. The bronchi and alveoli were slightly thickened but were otherwise normal.

The pericardium was clean and smooth and the pericardial cavity contained no fluid. The heart weighed 325 Gm. The myocardium was not thickened but showed very slight fibrosis. The coronary arteries were explored and found to be normal. The valves were not remarkable except for a slight thickening of the mitral valves.

The aorta showed marked atheromatous changes extending from the arch to the common iliac arteries. There was also

a small amount of lymphocytic infiltration in the tunica media and the tunica intima of the aorta. The renal arteries were moderately sclerotic but the other branches of the aorta were grossly normal. No abnormalities of the pulmonary vessels were noted.

The component parts of the gastro-intestinal tract were normal. The observations failed to explain the cause of the diarrhea and the black stools that were noted. The pancreas was normal. The spleen which weighed 125 Gm, was grossly normal but histologic examination revealed a few small areas of fibrosis and an increase in the amount of hematogenous pigment present.

The liver was enlarged and weighed 2,450 Gm. The surface was smooth and homogeneous in appearance and was light yellow. A normal amount of resistance was encountered in sectioning the organ. Cut surfaces showed normal lobulations, although the markings were fainter than usual. The extra-hepatic ducts and vessels were normal. Microscopically, the hepatic cells had undergone an acute fatty degeneration and the cytoplasm of each cell contained fat globules. In some portions of the slide, small areas of hemorrhagic necrosis could be seen. There was a moderate lymphocytic infiltration in the periportal spaces and a few polymorphonuclear leukocytes were present. The interlobular fibrous tissue was slightly increased and a number of new bile ducts had been formed. The liver was 65 per cent fat by weight and contained 0.03 mg of arsenic per hundred grams of tissue. Cultures taken from the liver on the autopsy table failed to demonstrate the presence of *Endamoeba histolytica*.

The kidneys weighed 225 Gm each and were slightly enlarged. Both organs were otherwise grossly normal except for a small retention cyst in the left kidney. On microscopic examination there were a few deposits of bile in the tubular epithelium, and a few areas of tubular necrosis were present. A large number of the cells lining the tubules had undergone cloudy swelling. The renal stroma showed a slight increase in fibrous tissue. The glomeruli were normal. The renal tissue contained 0.1 mg of arsenic per hundred grams. The remainder of the urinary system was normal. All the genital organs were atrophic.

The adrenals showed slight cortical degeneration and a few hematogenous pigment deposits. The other endocrine organs were normal.

TOXICITY OF CARBARSONE

As stated before, carbarsone is a relatively innocuous drug when compared to related arsenical compounds that also contain benzene rings. Anderson and Reed,³ in a series of 330 cases treated with carbarsone, found no evidence of skin, optic nerve or kidney damage. However, some of their patients experienced slight gastric upsets. One with a history of previous liver damage developed an acute hepatitis but this rapidly disappeared within five days after the withdrawal of the drug. In this series the total dosage ranged from 75 to 2,100 mg per kilogram of body weight given in divided doses over a period of fifteen months.

Ferrington⁴ has given graduated doses of carbarsone up to totals of 150, 300, 600, 800 and 1,200 mg per kilogram of body weight over a period of forty-eight weeks. This was given by administering the drug for four weeks and then following with a four weeks rest. In his series, Ferrington noted no evidence of toxicity according to clinical studies including visual field determinations, blood examinations and urinalyses at intervals of four weeks.

Minimum lethal dosage tables have been worked out for various laboratory animals.^{1a} This includes 150 mg per kilogram of body weight for guinea-pigs, 200 mg per kilogram of body weight for rabbits and

from 200 to 250 mg per kilogram of body weight for cats. This dose causes lethargy, loss of weight, abdominal distention, diarrhea, sluggish reflexes and failure of the pupils to respond to light. It should be noted that the patient described in this report exhibited all these signs and symptoms with the exception of the last named. Autopsies performed on animals given a minimum lethal dose of carbarsone showed necrosis of the kidney with tubular degeneration. When the dosage was confined to the therapeutic range, no signs of toxicity were noted and in those animals later killed by air embolism and examined anatomically no pathologic alterations were discernible.

In human beings a number of mild reactions have been reported, but none of these have led to serious consequences. One case was reported to the Council on Pharmacy and Chemistry of the American Medical Association in 1934.² This patient had received 0.25 Gm of carbarsone twice a day for six days. On the fourth day he complained of a headache and on the following day generalized pruritus was noted. On the sixth day a slight scaling erythematous eruption developed on the forearms. All signs of toxicity cleared within forty-eight hours after the withdrawal of the drug.

Dr. Frank Smithies⁵ reported a number of cases with reactions following carbarsone therapy before the

Chicago Society of Internal Medicine on May 28, 1934. One of these patients developed an exfoliative dermatitis of the hands and arms after less than ten capsules of 0.25 Gm each. Another patient was given twenty capsules of 0.25 Gm each and instructed to take one capsule three times a day. After the fifth day this patient developed laryngeal and pulmonary edema, sore throat, sneezing and lacrimation. Another patient was put on a regimen during which he took treatment for five weeks and then rested one week. Six weeks after the introduction of treatment, this patient developed acutely swollen ankles, knees and wrists and enlargement of the liver and spleen. A fourth patient developed faulty vision, photophobia, swelling of the eyelids and puffiness of the face. Urinalysis showed the presence of granular casts and albuminuria. Ophthalmoscopic examination revealed moderate papillitis and retinal edema. This followed the taking of a total of 175 Gm in three and one-half days. Several of Smithies' patients suffered from nausea, vomiting, diarrhea and vague abdominal pains while taking carbarsone. One of these developed a slight but definite icterus on the fourth day while taking 0.5 Gm of carbarsone daily.

As carbarsone contains a modified amino group in the para position to the arsenic atom, the possibility of the drug damaging the optic tract must always be considered and searched for in all patients under carbarsone treatment. Reed⁶ recommends the use of liver

⁵ Smithies Frank quoted in Council report.
⁶ Reed A. C. Amebiasis. A Clinical Summary. *California & West Med* 40: 6 (Jan) 1934.

function tests before prescribing carbarsone, as liver damage is a definite contraindication to its administration. Fantus⁷ recommends that the following signs of toxicity should be watched for in patients who are receiving carbarsone: gastro-intestinal irritation, congestion of the respiratory tract, neuritis, renal damage and visual disturbances. Pruritus, skin eruptions and enlargement of the liver or spleen should be added to this list.

Nothing has been written about the therapy of carbarsone poisoning. According to our present knowledge, treatment should be identical with that used in reactions to the other arsenical preparations.

COMMENT

Chemically, a very close relationship exists between carbarsone, acetarsone and tryparsamide. This is graphically portrayed by the chemical formulas of these substances.

With this in mind it is easy to comprehend why the reactions to these three drugs are so much alike. Stokes⁸ reports the following signs and symptoms of tryparsamide toxicity, which were also found in this patient: dermatitis, jaundice, hepatitis and slight irritation of abnormal kidneys. The same author⁸ lists the following reactions to acetarsone, which were present in this patient: malaise, headache, fever, edema, albuminuria, jaundice, eosinophilia, leukopenia and exfoliative dermatitis.

The recommended dose of carbarsone is 5 Gm given in divided doses over a period of ten days.^{1a} This may be repeated after a rest period. Accordingly, the patient did not receive an overdose of carbarsone but apparently died from a therapeutic dose. An accurate medical history of her last six weeks of life was obtainable and carbarsone is the only arsenical she received during this period.

Her liver damage was probably an acute process. The enlargement of the liver, the tenderness and rigidity in the right upper quadrant of the abdomen and the icterus developed while she was in the hospital. Histopathologic examination of the liver indicated an acute process, as there was little fibrosis or regeneration. With this evidence at hand, it is doubtful whether any drugs given previous to thirty days before entry could have been a major factor in causing her death.

It is true that the patient was in very poor condition before the carbarsone was administered. This may have reduced her tolerance to the drug. With our present knowledge, it can only be concluded that the patient developed signs of an idiosyncrasy to carbarsone within the therapeutic range and died despite withdrawal of the drug and active treatment for an arsenical exfoliative dermatitis.

SUMMARY

1. Carbarsone is less toxic in the therapeutic range when given by the therapeutic route of administration than most other related arsenical preparations but is not entirely innocuous.

2. Care must be taken in administering carbarsone and constant watch must be maintained for signs of intolerance.

1200 North State Street

WHAT IS THE SOCIAL OBJECTIVE OF THE YOUNG PHYSICIAN?

NATHAN B. VAN ETEN, MD
NEW YORK

Why do young people study medicine? Are they animated by high ideals of social service or the lure of pure science or the desire for social distinction or the hope of material reward?
